SCIENCE & ENGINEERING INDICATORS - 1989

NATIONAL SCIENCE BOARD

Cover Illustration

The illustration was supplied by Professor John H. Woodhouse, Department of Earth and Planetary Sciences, Harvard University. It depicts a section into the Earth showing a composite image synthesized from seismic tomographic mapping. Results from seismic tomography are being used to answer fundamental questions about the evolution and present-day dynamics of the Earth.

Lower than average velocities, which are indicative of elevated temperatures, are shown in orange; high velocities are shown in blue.

Details of the models and methodologies are available in Woodhouse and Dziewonski 1984 (*Journal of Geophysical Research* 89: 5953); Dziewonski 1984 (Ibid., p. 5929); Woodhouse, et al., 1986 (*Journal of Geophysical Research Letters* 13: 1549); and Morelli, et al., 1986 (Ibid., p. 1545).

Letter of Transmittal

December 1, 1989

My Dear Mr. President:

In accordance with Sec. 4(j)(1) of the National Science Foundation Act of 1950, as amended, it is my honor to transmit to you, and through you to the Congress, the ninth in the series of biennial *Science Indicators* reports—*Science & Engineering Indicators—1989*.

These reports are designed to provide a broad base of quantitative information about U.S. science and engineering research and education and U.S. technology in a global context to be used by public and private policymakers in their decisions about these activities.

The data and analyses in this volume are especially important as our Nation seeks to define its priorities and programs in this era of rapid global economic, political, and social change. The key role of science and technology in achieving our national objectives is recognized by Government and industry, and is reflected in their support of this function.

This report follows its predecessors in providing basic information on U.S. and foreign:

- Research and development efforts, support, and performance;
- School science and mathematics education;
- Higher education for science and engineering;
- The science and engineering workforce;
- Technological innovation and high-technology trade; and
- Public science literacy and attitudes toward science and technology.

New features in this volume include materials on high school course-taking in science and mathematics, state support for R&D, "modeling" the science and engineering labor market, comparisons of U.S. and Japanese patenting in the United States, a "global" approach to analysis of data on production and trade in high-tech goods, and comparisons of U.S. and British public attitudes toward science and technology.

I join my colleagues on the National Science Board in expressing the hope that this report will be useful to your Administration, the Congress, and those concerned with formulating and analyzing science and technology policy.

Respectfully yours,

Mary L. Good

Mary L. Good
Chairman, National Science Board

The Honorable
The President of the United States
The White House
Washington, D.C. 20500

Contents

Introduction

This volume is the ninth in the biennial *Science Indicators* series (and the second entitled *Science & Engineering Indicators*) initiated by the National Science Board (NSB) in 1972. The series provides a broad base of quantitative information about the structure and function of U.S. science and technology (S&T) and comparisons with other advanced industrial countries. It is designed to both inform national policymakers who allocate resources to these activities and serve as an information resource to the S&T community at large.

The Basic Question of Science and Technology Policy

In this era of rapid global change, the Nation's key S&T policy concern is to identify the kinds, levels, and emphases of the national effort in science and engineering research and development (R&D) and education in order to:

- Produce sustained advances across a broad front in the understanding of natural and social phenomena (basic research);
- Foster vigorous inventive activity to produce continuing technological progress (applied research and development);
- Combine understanding and invention in the form of socially useful and cost-effective products, processes, and services (innovation); and
- Ensure an adequate supply of highly trained and talented scientists and engineers to meet the Nation's needs.

Creating Science and Technology Indicators

The science, engineering, and technology system is less easy to measure than other major functional areas of our society such as health, agriculture, or the economy. This is due in good part to the nature of its primary output—knowledge and ideas. People create, communicate, and carry ideas; dollars support people. We can and do track people and dollars. But we still are unsophisticated in our attempts to measure either science as a body of ideas or its connections with the social and economic order. Thus, our indicators remain—for now—largely measures of aspects of science and engineering *as sets of activities*, rather than as *particular bodies of knowledge*.

The elements of the science, engineering, and technology system in the U.S. can be specified as:

- The *human resources*, including working scientists and engineers and their technical support and technical managers and entrepreneurs;
- The various *organizational settings* for conducting R&D and technical education;
- The substantive *findings, research methods, and theories* embodied—in large part—in science and engineering literatures;
- The *physical infrastructure*, including research and teaching facilities and instrumentation with the most advanced capabilities;
- The necessary *financial support* for all of these elements; and
- A *cultural, economic, and legal context* that is supportive of these efforts.

While easy to specify in principle, describing each element and subelement in the system involves many problematic research issues. For example, what operational definitions should be used for counting scientists and engineers? Should it be their formal degrees? Their past work experience? Their current work activity? And, if all three, in what combination? In what sense do the data on U.S. patents awarded reflect rates of technical innovation? Does the dramatic increase in coauthorship of scientific publications reflect real change in the conduct of research?

Even more difficult are the problems of tracking and analyzing the interactions among these imperfectly measured elements—the dynamics of the system.

Continuing investigation into these questions is a *sine qua non* of improved indicators, and the National Science Foundation (NSF) does provide modest funds for extramural studies in this area. (See the Science Indicators Group Program Announcement, available upon request.) Descriptions of NSF-supported projects currently under way are available in *Project Summaries: FY 1987* (NSF 87-315).

About half of the quantitative information in this volume is generated by the national surveys and studies conducted on a continuing basis by NSF's Division of Science Resources Studies (SRS). The Division's *Publications List: 1978-1988* (NSF 88-335) details these studies; it also explains how to obtain detailed statistical tables from the various surveys (on computer diskettes), and data sets from the SRS Electronic Bulletin Board. Additionally, the *Publications List* references extramural publications deriving from SRS-supported studies. For further information, call (202) 634-4634.

This volume also contains considerable information obtained from outside NSF. The original sources are noted throughout the text and tables. In the case of analyses specially commissioned for this volume, the Science Indicators Group staff can provide further information. Call (202) 634-4682.

What Is New in This Volume?

Following the extensive structural changes in *Science & Engineering Indicators—1987*, the approach in the present

volume has been to consolidate and refine those changes. However, a number of new features are also incorporated.

- A major new study of high school transcripts is analyzed in the precollege education chapter (chapter 1).
- For the first time, data about colleges and universities are broken out by the Carnegie categories of institutions in the chapter on higher education (chapter 2).
- A new "stock-flow" model for analyzing the dynamics of the science and engineering labor market is presented in the chapter on the workforce (chapter 3).
- The chapter on financial support for R&D includes a new section on state support for R&D (chapter 4).
- A new treatment of industrial support of academic R&D is included in the chapter on academic R&D, as is new bibliometric information on the growth of coauthorships of scientific papers (chapter 5).
- New comparisons of patterns of Japanese and U.S. patenting in the U.S. are presented in the chapter on industrial R&D (chapter 6).
- The title of the international chapter has been changed to "The Global Markets for U.S. Technology," reflecting a new approach to the area which includes U.S. internal markets for high-tech goods as an integral part of the analysis (chapter 7).
- The move toward international comparative materials on public attitudes towards science and technology, initiated in the 1987 *Indicators*, is continued in the present volume with comparative data from a parallel British survey (chapter 8).

Additionally, we have incorporated several new presentation techniques for enhanced readability and reader accessibility. These include "sidebar" stories accompanying the main text, changed Highlights formats, chapter-specific tables of contents, and a list of acronyms (appendix III).

Organizational Responsibilities

This volume is a collaborative effort, as can be seen in the acknowledgments below and in appendix II. The overall responsibility for the report derives from the statutory charge to the National Science Board [Sec. 4(j)(1) of the National Science Foundation Act of 1950, as amended]. A special committee of NSB members provided oversight and guidance to the staff of the Science Indicators Group of the Special Analytical Studies Section of the Division of Science Resources Studies, who worked exclusively on the report and related research. Other members of SRS, as well as staff from other NSF Directorates, aided in manuscript preparation. Numerous external expert reviewers and users helped to shape and sharpen the indicators. Overall staff responsibility for the report was assumed by NSF's Directorate for Scientific, Technological, and International Affairs.

Acknowledgments

The National Science Board extends its appreciation to the following members of the National Science Foundation (NSF) who provided primary assistance in the preparation of this report.

Organizational responsibility was assigned to the Directorate for Scientific, Technological, and International Affairs (STIA):

Richard J. Green, Assistant Director (to 12-15-88)
Richard R. Ries, Acting Assistant Director (to 9-1-89)
F. Karl Willenbrock, Assistant Director (from 9-1-89)

The draft manuscript was produced in the Division of Science Resources Studies (SRS) under the guidance of:

William L. Stewart, Director
Leonard L. Lederman, Head, Special Analytical Studies Section
Carlos E. Kruytbosch, Director, Science Indicators Group

The manuscript was written by the following NSF staff.

SRS Science Indicators Group:
Lawrence Burton—Chapters 2 and 4, contribution to 5
Donald E. Buzzelli—Chapter 8 and part of 6
Barbara B. Mandula—Chapter 5
Lawrence M. Rausch—Chapter 7 and part of 6

SRS Employment Studies Group:
R. Keith Wilkinson—Chapter 3

Directorate for Science and Engineering Education:
Richard M. Berry—Chapter 1

The production process was directed by Lawrence M. Rausch; primary statistical support was provided by Theodosia (Dottie) Jacobs of SRS; secretarial services were provided by the members of the SRS Administrative Support Group under the direction of Joanne Streeter. Valuable guidance in editorial and production matters was provided by Nita Congress and Patricia Hughes.

The Board is also grateful to the special contributors to and reviewers of *Science & Engineering Indicators—1989*, all of whom are listed in appendix II.

Overview of U.S. Science and Technology

CONTENTS

Overview of U.S. Science and Technology

SYNOPSIS

The decade-long (1975-85) uninterrupted expansion of support for U.S. science and technology (S&T) has leveled off in recent years (1985-89). With some important exceptions, most indicators of U.S. S&T show significant slowdowns and downturns. For example:

- Growth rates have slowed in both research and development (R&D) funding and science and engineering (S/E) personnel.
- While the U.S. still spends more on R&D than the next four industrialized countries combined, some international competitors (e.g., Japan and West Germany) have drawn ahead of the U.S. in terms of R&D expenditures as a percentage of gross national product (GNP).
- In several areas, U.S. producers of high-tech goods have lost significant global market shares.
- National and international indicators of U.S. school mathematics and science performance show little improvement, despite continuing major reform efforts.
- U.S. university and college freshmen show a downward trend in their choice of undergraduate majors in some S/E fields. Although undergraduate S/E degrees awarded have remained at about 30 percent of all bachelor's degrees awarded for the past 3 years, the freshman shift away from S/E majors portends reduced S/E degrees in coming years.
- Increases in graduate S/E enrollments (in doctorate-granting universities) slowed from an average annual rate of 2 percent from 1980 to 1987 to a 1-percent increase from 1987 to 1988.
- Foreign students continued to increase (and U.S. citizens to decrease) their share of graduate S/E enrollments and S/E Ph.D. degrees granted by U.S. universities in all broad S/E fields except psychology.
- One area of continuing growth (albeit at a slightly slower rate than that of the past decade) is support for basic research and R&D in universities and colleges. This support has no doubt assisted the U.S. in maintaining its share of world scientific and technical literature.

Support for U.S. R&D continues to grow in constant-dollar terms, but at a much slower rate than has been the case for the previous decade and a half. Although total R&D expenditures grew at an annual rate of almost 6 percent from 1975 to 1985, the rate of growth for 1986 to 1989 is estimated at about 2 percent per annum.

The slower pace of U.S. R&D growth in recent years is also reflected in a U.S. lag of 3 consecutive years behind Japanese and West German R&D expenditures as a percentage of GNP.

The recent slowdown in funding growth is most dramatic for the development and applied research components of R&D (1-percent estimated annual growth rate from 1986 to 1989); basic research expenditures slowed only slightly to an estimated annual growth rate of 3 percent (in constant dollars). These trends are largely due to two sets of policy decisions. First, Federal S&T policy has moved toward reducing the rate of increase in defense R&D spending and toward maintaining growth in basic research and academic R&D. And in the industrial sector, corporate R&D decisionmakers have slowed their rate of growth in company funding of R&D.

While the U.S. continues to be the world's foremost supplier of high-tech products, its lead is shrinking. The U.S. share of global markets for high-tech goods, which declined during the 1970s and then recovered in the first half of the 1980s, showed renewed weakness in the latest period measured (1985-86). During this period, U.S. producers lost both domestic and foreign market shares. However, the U.S. trade balance in high-tech goods showed a slight upturn back into a positive balance in 1987; this followed a 7-year period of decline and a first-ever deficit in 1986. In terms of innovation, U.S. patent applications and awards—both indicators of a country's S&T innovation—have increased in the recent period, but not as rapidly as foreign patenting in the United States.

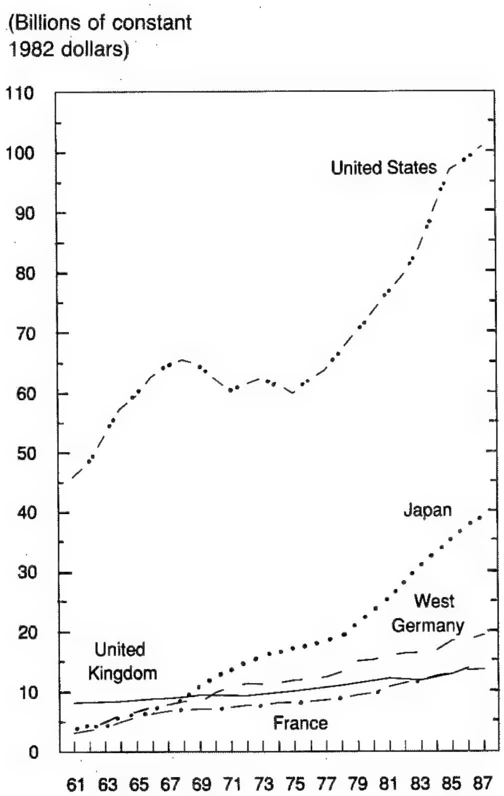
Since measurements began in 1957, the U.S. public has exhibited strong positive beliefs about the beneficial contributions of science and technology to society. Data from a 1988 survey of public attitudes toward S&T showed a reaffirmation of public confidence in the societal benefits of S&T. Previously, such confidence had wavered somewhat, as detected in two surveys conducted after the National Aeronautics and Space Administration space shuttle accident in January of 1986 and the Chernobyl nuclear plant accident the following May.

U.S. R&D INVESTMENTS IN A WORLD CONTEXT

In the world context, the United States spends more on R&D than the next four largest countries—Japan, West Germany, France, and the United Kingdom—combined. Over the past decade, the U.S. has more or less maintained its share of the combined R&D budgets of the five countries: 56 percent in 1975 versus 54 percent in 1986. This share was significantly reduced from the 68-percent share the U.S. enjoyed in 1966. (See figure O-1.)

Despite the differences in total expenditures, in 1987, the major noncommunist industrialized countries each invested approximately the same percentage of their GNPs in R&D. (See figure O-2.) Both Japan and West Germany have now exceeded the U.S. on this indicator for 3 years (1985-87).

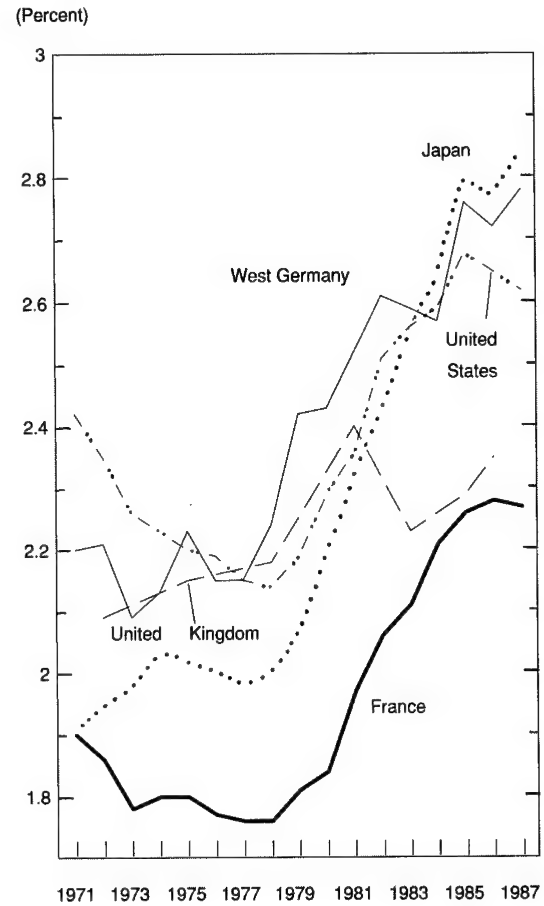
Figure O-1.
R&D expenditures, by country: 1961-87



Note: Some data are estimates.
See appendix table 4-19 and p. 96.
Science & Engineering Indicators—1989

The nature of R&D investments has an important bearing on their economic contributions. If only nondefense R&D is considered, Japan and West Germany have been ahead of the U.S. for nearly two decades; additionally, their rate of civilian R&D investment as a percentage of GNP has been rising faster than that of the U.S. since 1981. (See figure O-3.) U.S. investment in nondefense R&D as a percentage of GNP has declined for at least 2 years.

Figure O-2.
R&D expenditures as a percentage of GNP, by country



Note: Data for some years are estimated.
See appendix table 4-19 and p. 96.
Science & Engineering Indicators—1989

The overall rate of increase of U.S. R&D expenditures has slowed considerably in recent years. While total national expenditures for R&D grew at an annual rate of almost 6 percent from 1975 to 1985 (in constant dollars), the rate of growth for the most recent period (1986-89) is estimated at only about 2 percent annually. The rapid rate of increase of development funding in the early 1980s has shrunk to an estimated annual rate of less than 1 percent in 1989. On the other hand, funding for basic research has continued to grow at only slightly less than its 1975-85 rate. (See figure O-4 and appendix table 4-5.)

Changing growth rates in U.S. R&D expenditures are also evident in figure O-5, which displays defense and nondefense R&D by character of work. The massive increase in defense development expenditures from 1980 to 1985 was reduced to a very small growth rate by 1989. In civilian R&D, basic research maintained a significant growth rate in both periods, while civilian applied research and development expenditures remained approximately constant from 1986 to 1989 after suffering large cuts between 1980 and 1985.

Science & Engineering Indicators—1989

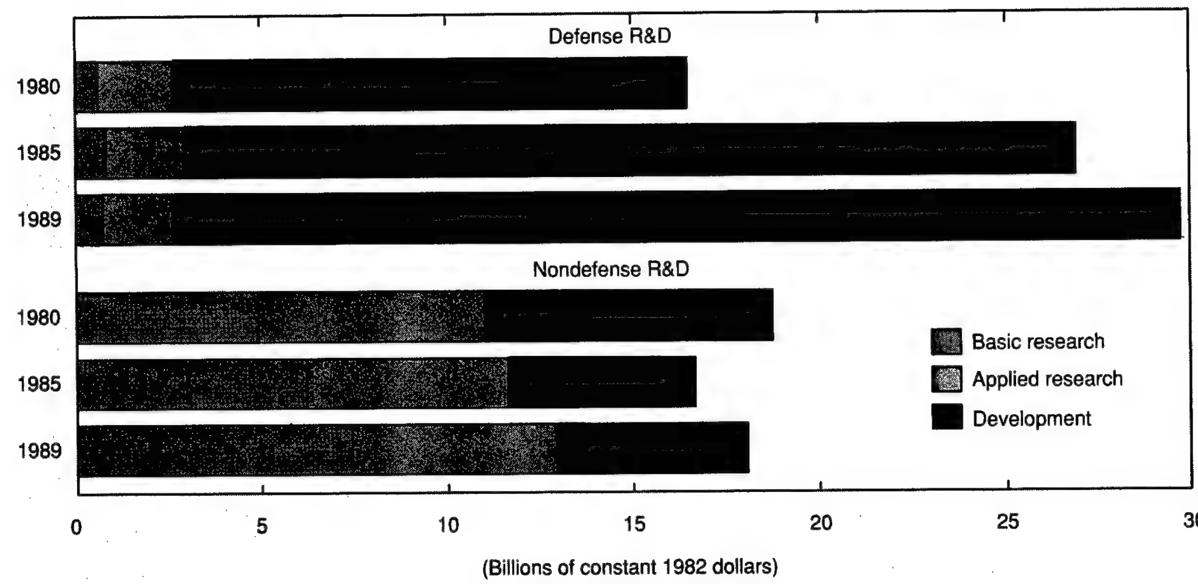
HUMAN RESOURCES

International Comparisons

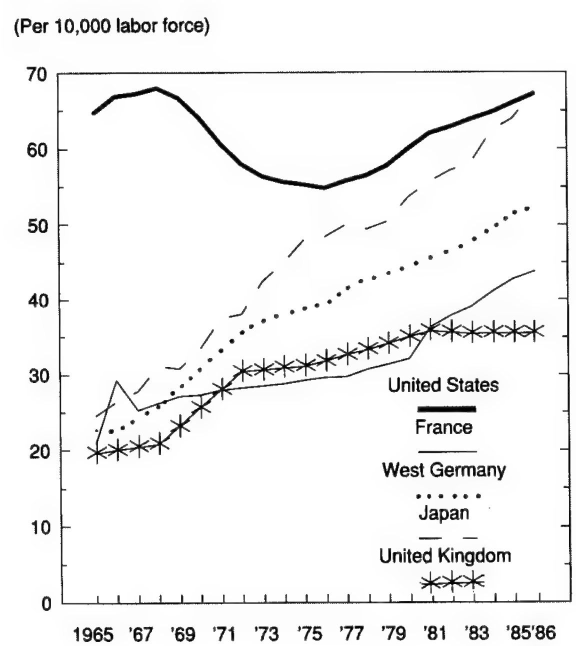
Recent years (1984-86) have seen a slowing in the rate of growth of U.S. scientists and engineers engaged in R&D per 10,000 workers in the labor force. After two decades of rapid growth, Japan has now caught up with—and, in fact, slightly exceeds—the U.S. on this indicator. Japan has 67 researchers per 10,000, compared with 66 for the United States. France and West Germany continue to increase at about the same rate as the U.S., while in the United Kingdom, the growth of researchers in the labor force has remained flat since 1981. (See figure O-6.)

Figure O-5.
Relative changes in Federal obligations for defense and nondefense R&D, by character of work



See appendix table 4-13 and p. 94. *Science & Engineering Indicators—1989*

Figure O-6.
Scientists and engineers engaged in R&D per 10,000 labor force, by country



See appendix table 3-19 and p. 76.
Science & Engineering Indicators—1989

Closely paralleling the international comparative data on R&D funding, the U.S. in 1986 awarded more first academic degrees in natural science and engineering (NS/E) than the next four largest noncommunist countries combined—about 214,000 persons versus about 175,000, respectively. (See appendix table 3-18.) The five countries also vary considerably in the proportion of first academic degrees that are in NS/E fields, as well as in the relative proportions of natural science to engineering degrees. (See figure O-7.) The U.S. and Japan have the smallest proportions of all first university degrees in NS/E fields—20 percent and 26 percent, respectively—while France and the United Kingdom have the highest proportions (47 percent and 40 percent, respectively). Among the NS/E fields in Japan and France, first engineering degrees outnumber natural science degrees—in Japan, by a factor of four to one. In 1986, Japan—which has half the population of the U.S.—graduated about 73,000 engineers, a number almost equal to U.S. engineering degrees awarded in that year (77,000). In contrast, in both the U.S. and the United Kingdom, natural science degrees outnumber engineering degrees by nearly two to one.

Private Sector Employment of U.S. Scientists and Engineers

Between 1977 and 1988, S/E employment in the private sector expanded at more than twice the rate of total employment.

This trend encompassed major changes in the occupational and industrial mix of S/E employment. For example, S/E employment in services-producing industries grew 103 percent over the period, compared to a 38-percent growth in total services employment. (See figure O-8.) S/E employment growth in the goods-producing sector stemmed from an increased share of a declining total in manufacturing jobs.

The expansion of the services-producing industries has been a key factor in the extraordinarily rapid growth of computer specialists between 1980 and 1988. (See figure O-9.)

Figure O-7.

Note: Numbers are for 1988 S/E employment
See appendix table 3-2 and p. 66.

Science & Engineering Indicators—1989

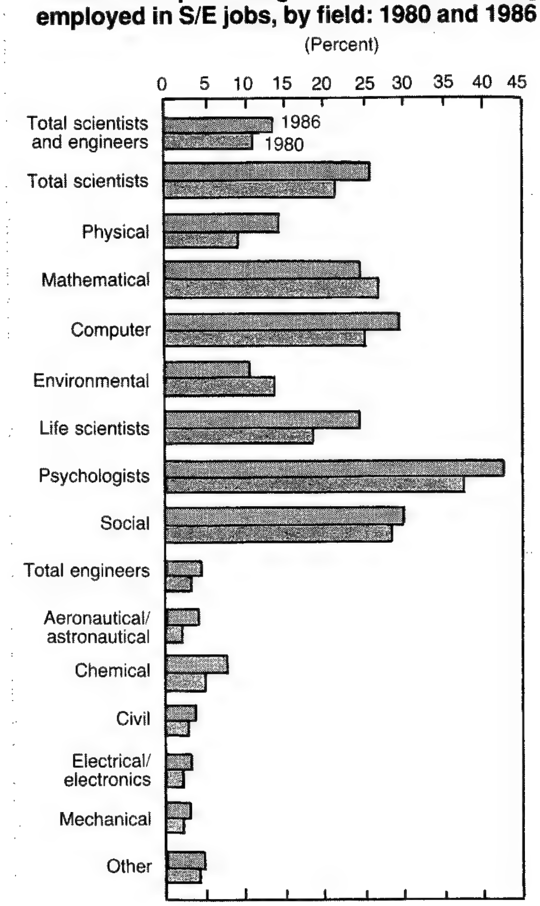
Women in S/E

Women scientists and engineers represented about 13 percent of the S/E workforce in 1986, up from 11 percent in 1980. (See figure O-10.) By field, women accounted for a much larger share of employment among scientists than among engineers—26 percent versus 4 percent. Between 1980 and 1986, women experienced small percentage losses in the mathematics and environmental sciences, but achieved sizeable gains in the physical and life sciences. Small percentage gains were made in all engineering subfields.

Precollege Science and Mathematics Education

U.S. school children continue to perform below the levels obtained by their age groups in other countries on science and mathematics achievement tests. In a 1988 international mathematics and science assessment of 13-year-olds in five countries and several Canadian provinces, U.S. children scored lowest of all the populations in mathematics and below the mean in science. (See figure O-11.)

Figure O-10.
Women as a percentage of scientists and engineers employed in S/E jobs, by field: 1980 and 1986



See appendix table 3-2 and p. 67.

Science & Engineering Indicators—1989

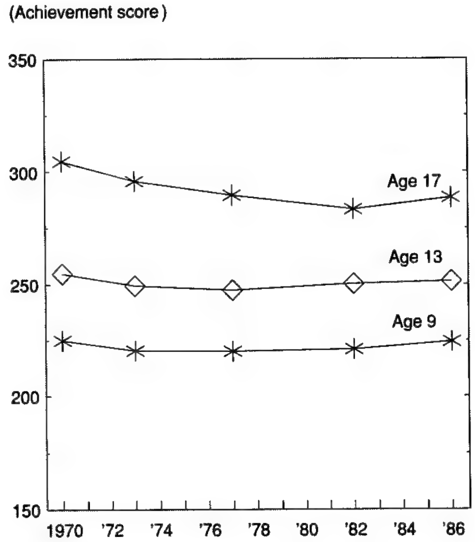
See appendix tables 1-11 and 1-12 and pp. 27-28.

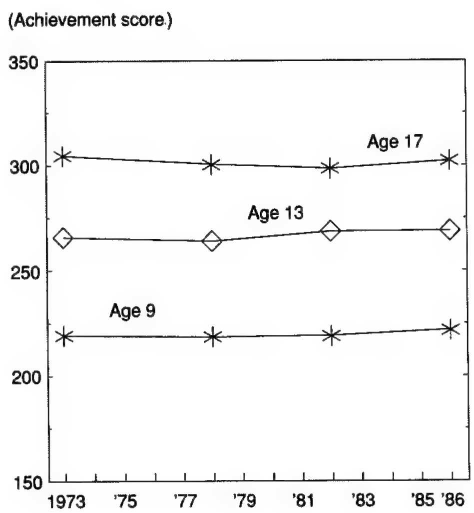
Science & Engineering Indicators—1989

Figure O-12.
National trends in average science achievement: 1970-86



See appendix table 1-1 and p. 22.
Science & Engineering Indicators—1989

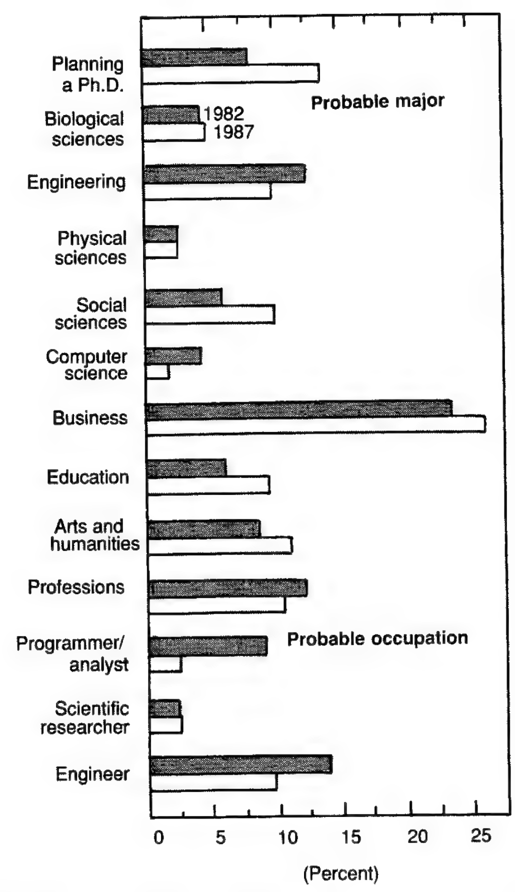
Figure O-13.
National trends in average mathematics achievement: 1973-86



See appendix table 1-6 and p. 24.
Science & Engineering Indicators—1989

There are signs, however, that the two-decade-long decline in mathematics and science achievement test scores of U.S. children may be turning around. Slight improvements in science and mathematics achievement trends were detected in the 1986/87 National Assessment of Educational Progress studies. (See figures O-12 and O-13.) Trends for 9-, 13-, and 17-year-olds across five national assessments in science since 1970, and four in mathematics since 1973, reveal a pattern of initial declines followed by subsequent recovery in all three age groups. In mathematics, 9- and 13-year-olds scored slightly higher in 1986 than in 1973. Scores for 17-year-old students, however, showed small declines. In science, the recent improvements have not yet brought scores up to their 1969 levels in any age group.

Figure O-14.
Freshman plans: 1982 and 1987



See text table 2-1 and pp. 50-52. *Science & Engineering Indicators—1989*

Higher Education

The interest of U.S. university and college freshmen in computing and engineering majors continues to decline. (See figure O-14.) However, a small increase in interest in a biological science major is apparent in the latest data, as well as renewed interest in the social sciences. Business, education, and the arts and humanities all register gains in student interest as evinced by choice of major.

While S/E degrees have remained about 30 percent of all bachelor's degrees in recent years, the downturn in freshman choice of S/E majors portends a reduction in S/E degrees in coming years. (See appendix tables 2-11 and 2-12.) Despite an increase in freshman engineering enrollments in 1988, decreases in engineering baccalaureates should continue for several years due to declining enrollments from 1983 to 1987. (See appendix table 2-5.)

At the graduate level, overall enrollments in science and engineering programs increased by 1 percent in 1988 over 1987, a significant drop from the 1980-87 trend of an average annual 2-percent increase. (See figure O-15.) Engineering, computer science, and environmental science enrollments show the most dramatic declines. However, several science fields experienced increased rates of enrollment. These included the life and social sciences, psychology, and mathematics.

Figure O-16.
Foreign enrollment in S/E graduate programs: 1980-88

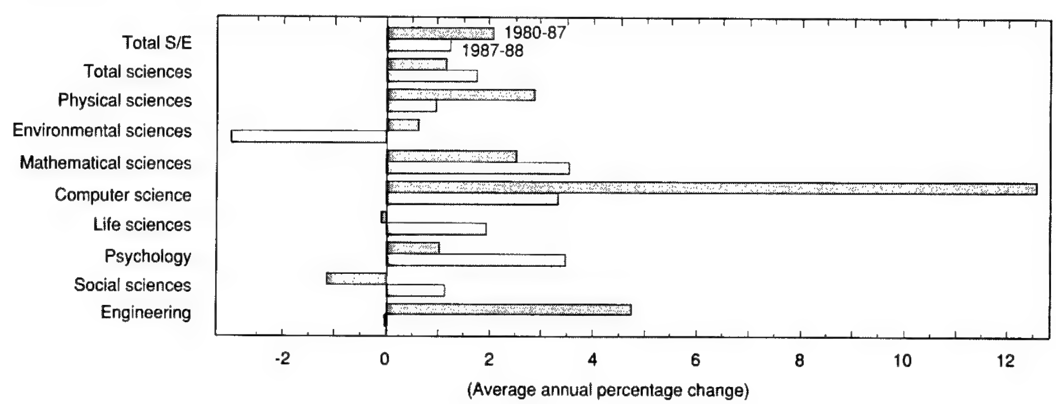
Change in graduate enrollments, by field



Note: Includes only enrollment in doctorate-granting institutions. See appendix table 2-7 and p. 53.

Science & Engineering Indicators—1989

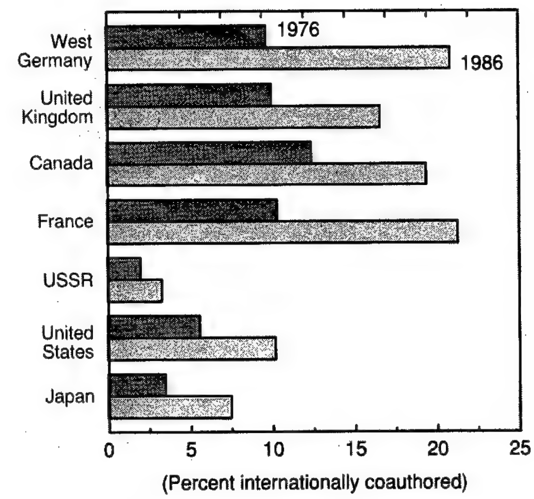
Text table O-1. U.S. share of world scientific and technical articles, by field: 1973, 1981, and 1986

	1973	1981	1986
		Percent	
All fields	38	36	36
Clinical medicine	43	41	40
Biomedicine	39	40	38
Biology	46	38	38
Chemistry	23	20	22
Physics	33	29	30
Earth/space sciences	47	43	43
Engineering/technology	42	41	37
Mathematics	48	38	40

See appendix table 5-23 and p. 120.

Science & Engineering Indicators—1989

Figure O-17.
Internationally coauthored articles, by country: 1976 and 1986



Note: An article is attributed to a country if one or more authors is from that country.
See appendix table 5-28 and p. 121.

Science & Engineering Indicators—1989

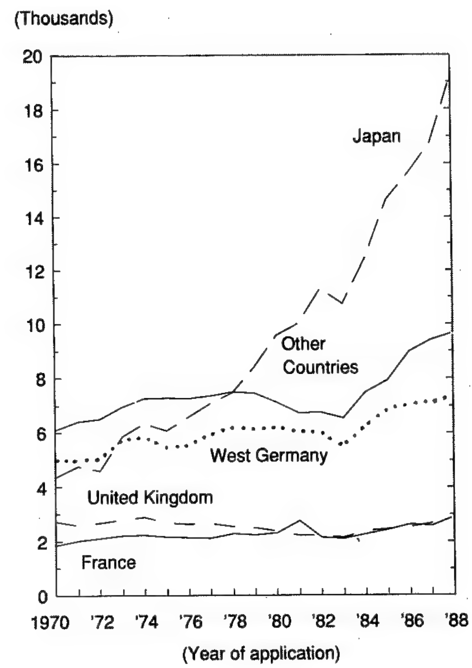
Growth in graduate S/E enrollments—albeit slowed—continues to be fueled by registrations of non-U.S. citizens. In doctorate-granting institutions, registration in graduate S/E programs of non-U.S. citizens accounted for the entire growth in total enrollments from 1987 to 1988. (See appendix table 2-8.) Non-U.S. citizens on temporary visas make up more than a third of S/E graduate students in engineering, mathematics, computer science, and the physical sciences. (See figure O-16.)

KNOWLEDGE CREATION AND APPLICATION

One measure of the relative strength of U.S. scientific research is the share of articles written by U.S. authors in the world's leading S/E journals. From 1973 to 1986, the U.S. more or less maintained its share of a little over one-third of world articles in most fields. Erosion of the U.S. share occurred in biology and mathematics—each of which lost 8 percentage points of its world share during this period. (See text table O-1.)

The data on international coauthorship of scientific articles suggest an increasing internationalization of scientific research. In the 1976-86 decade, most of the major countries studied virtually doubled the percentage of their papers coauthored with foreigners. (See figure O-17.) About 10 percent of all U.S. papers were coauthored with one or more foreign authors in 1986, as compared with about 6 percent in 1976. Western European countries ranged from 15 percent to 20 percent; Japan and the USSR had the lowest rates of foreign coauthorship.

Figure O-18.
U.S. patents granted to foreign inventors, by nationality of inventor



Note: Estimates are shown for 1981-88.
See appendix table 6-6 and pp. 135-36.

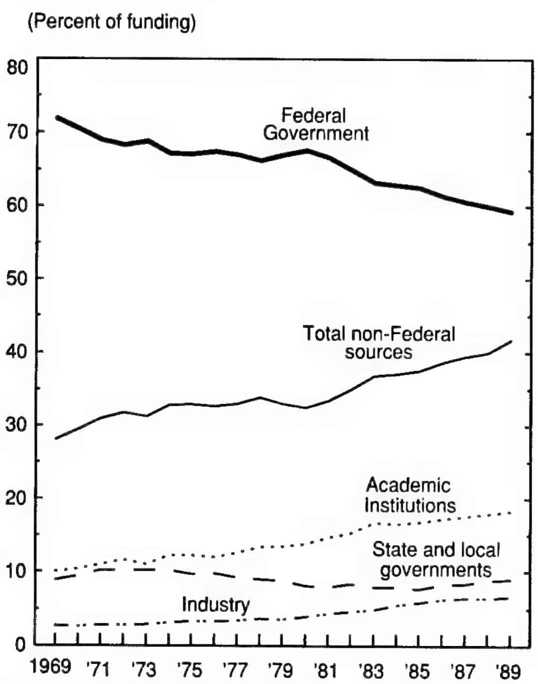
Science & Engineering Indicators—1989

U.S. inventors are increasing their numbers of successful patent applications in the U.S., but foreigners are acquiring U.S. patents at a significantly faster rate than are U.S. applicants. From application date 1970 to 1983, the annual number of U.S. patents granted to U.S. inventors fell from about 46,000 to 34,000, but has risen to about 45,000 in 1988. (See appendix table 6-6.) However, the proportion awarded to foreigners of all successful patent applications rose from 30 percent in 1970 to nearly half (48.5 percent) in 1987. Japanese inventors were by far the most active in increasing their U.S. patenting. (See figure O-18.)

RESEARCH AND DEVELOPMENT

The relative magnitudes of the various R&D-performing sectors in the U.S. have stayed fairly constant over the decades, with some slight fluctuations. Industry has performed around three-quarters of all R&D, Federal laboratories and academic institutions around 10 percent each, and other entities around 5 percent. (See appendix table 4-2.) The very rapid growth of R&D in industry and government during the early 1980s has been replaced by growth rates of less than 2 percent in the late 1980s. Only the academic sector shows a higher rate of R&D growth in the late 1980s than in the earlier part of the decade. (See figure O-19.)

Figure O-20.
Source of academic R&D funding, by sector: 1969-89



Note: Data for 1988 and 1989 are estimates.
See appendix table 5-2 and p. 108.

See appendix table 4-2 and p. 87.
Science & Engineering Indicators—1989

The continuing growth of academic R&D is being achieved (in some measure) with increasing support from non-Federal sources. (See figure O-20.) Institutional and industrial sources of support show a slow—but consistent—pattern of increased R&D funding over the past two decades, with quickening support in the 1980s. All fields of academic R&D have shared in this growth, but to differing degrees. (See figure O-21.) The most rapid rate of expansion of academic R&D expenditures has taken place in computer science, engineering, and the mathematical sciences, but the medical and biological sciences continue to lead in absolute expenditures.

Figure O-21.

Science & Engineering Indicators—1989

SCIENCE AND TECHNOLOGY IN THE MARKETPLACE

U.S. High-Technology Performance in Global Markets

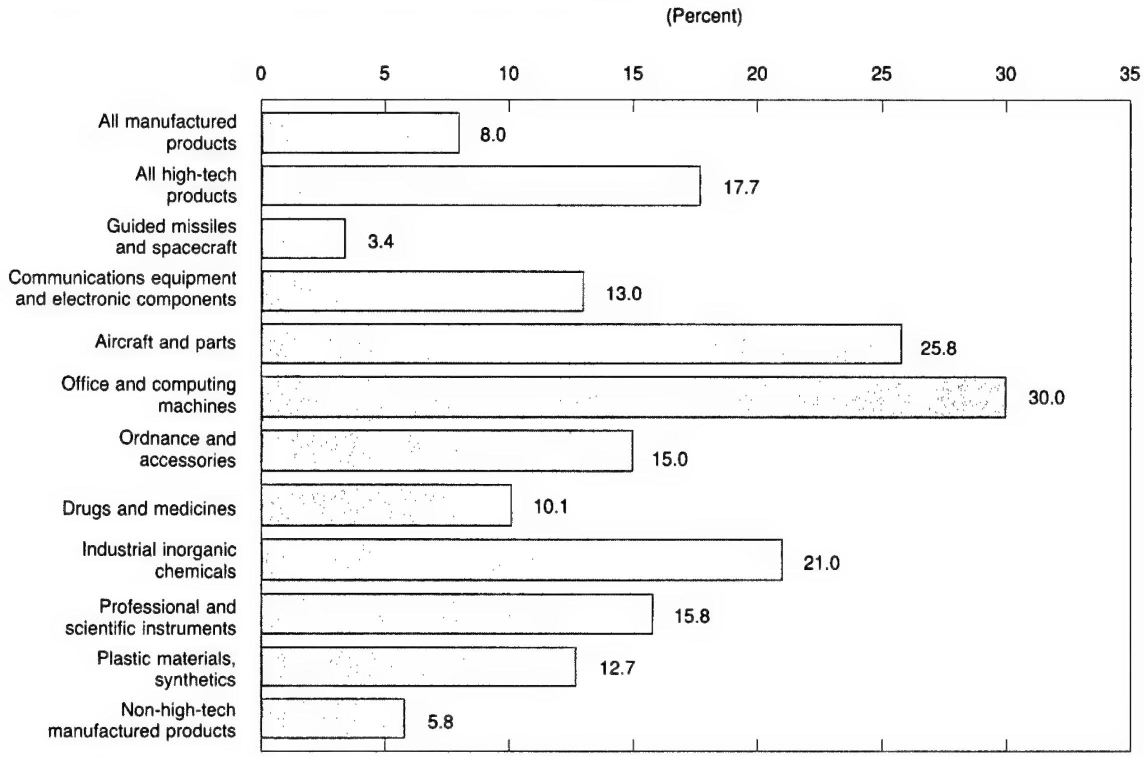
From 1970 to 1986, U.S. producers of high-tech goods decreased their share of global markets for such goods from about 50 percent to 40 percent. (See figure O-22.) However, almost all of this loss was due to a reduced share of domestic U.S. markets for high-tech goods. The share of world non-U.S. markets for U.S. high-technology producers actually increased slightly during the period.

U.S. producers of high-tech goods export about three times the percentage of their total shipments as compared with producers of non-high-tech manufactured products. (See figure O-23.) There has been little change over the past decade in the areas of high-technology where U.S. producers are most active in exporting. Aircraft and parts and office and computing machines remain the most export-intensive industries, and drugs and medicines, plastic materials and synthetics, and guided missiles and spacecraft the least.

Science and Technology in U.S. Industry

The latest estimates of U.S. industrial R&D activity show a flattening rate of increase of R&D expenditures after 1985. The previous decade (1975-85) saw continuous growth of industrial R&D from both corporate and Federal sources. (See figure O-24.) There was virtually no real growth in Federal funds for industrial R&D from 1985 to 1986. Company funds for R&D have continued to grow,

Figure O-23.
Exports of high-tech products as a percentage of shipments: 1986



See appendix table 7-9 and p. 153. *Science & Engineering Indicators—1989*

but at a much slower rate than during the decade before 1985.

During the 1975-85 decade, high-tech industries exhibited the bulk of the rapid growth in corporate R&D. Estimates for 1986 (the latest year for which industrial R&D data are available by industry) show a downturn in R&D expenditures (in constant 1982 dollars) in the high-tech manufacturing industries. (See figure O-25.) This trend may be slightly exaggerated—as may be the opposite upward trend in R&D expenditures among "other manufacturing industries"—by changes in the classification of certain major companies. But the principal finding of a slowdown in R&D expenditures among high-tech manufacturing companies is not in dispute.

Through 1987, industry continued to increase its support of R&D in universities. (See figure O-20.) In that year, industry supplied a record high of 6.4 percent of total academic R&D funds. The continuing interest of corporations in university research is also reflected in the increased rate at which industrial and academic scientists and engineers collaborate in authoring scientific papers. (See figure O-26.) The percentage of all industrially authored papers which are coauthored with academic researchers almost doubled between 1976 and 1986 (15 percent and 28 percent, respectively).

Science & Engineering Indicators—1989

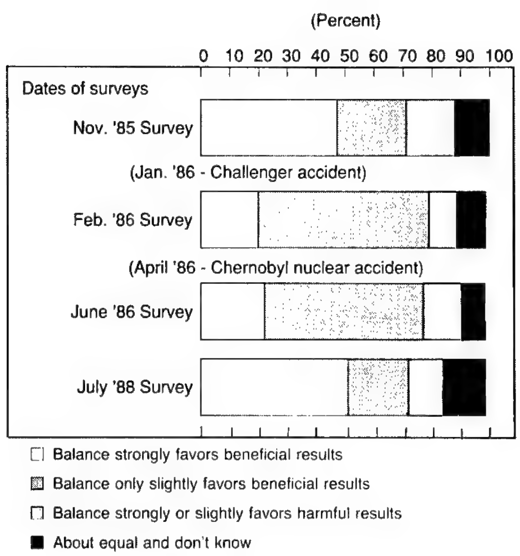
PUBLIC ATTITUDES TOWARD SCIENCE AND TECHNOLOGY

Over the decades, the U.S. public has held a remarkably stable and optimistic view of the contributions of science to society. This stability persists even in the face of major technological accidents. Figure O-27 shows the changes in U.S. public opinion as reflected in surveys before and after the Challenger and Chernobyl accidents.

A fall 1985 survey showed the traditional finding that about three-quarters of the U.S. public believe that, on balance, the benefits of scientific research outweigh the harms to society. In addition, as in previous surveys, those who believe that the benefits "strongly" outweigh the harms outnumber those who believe that the benefits "only slightly" outweigh the harms by a margin of two to one.

Figure O-27.
Beliefs about beneficial versus harmful effects of scientific research: 1985-88



"Would you say that, on balance, the benefits of scientific research have outweighed the harmful results, or have the harmful results been greater than the benefits?" "Would you say that the balance has been strongly in favor of beneficial results, or only slightly?"

Note: The same persons were interviewed in the 1985 and 1986 surveys. See appendix table 8-17 and p. 176.

Science & Engineering Indicators—1989

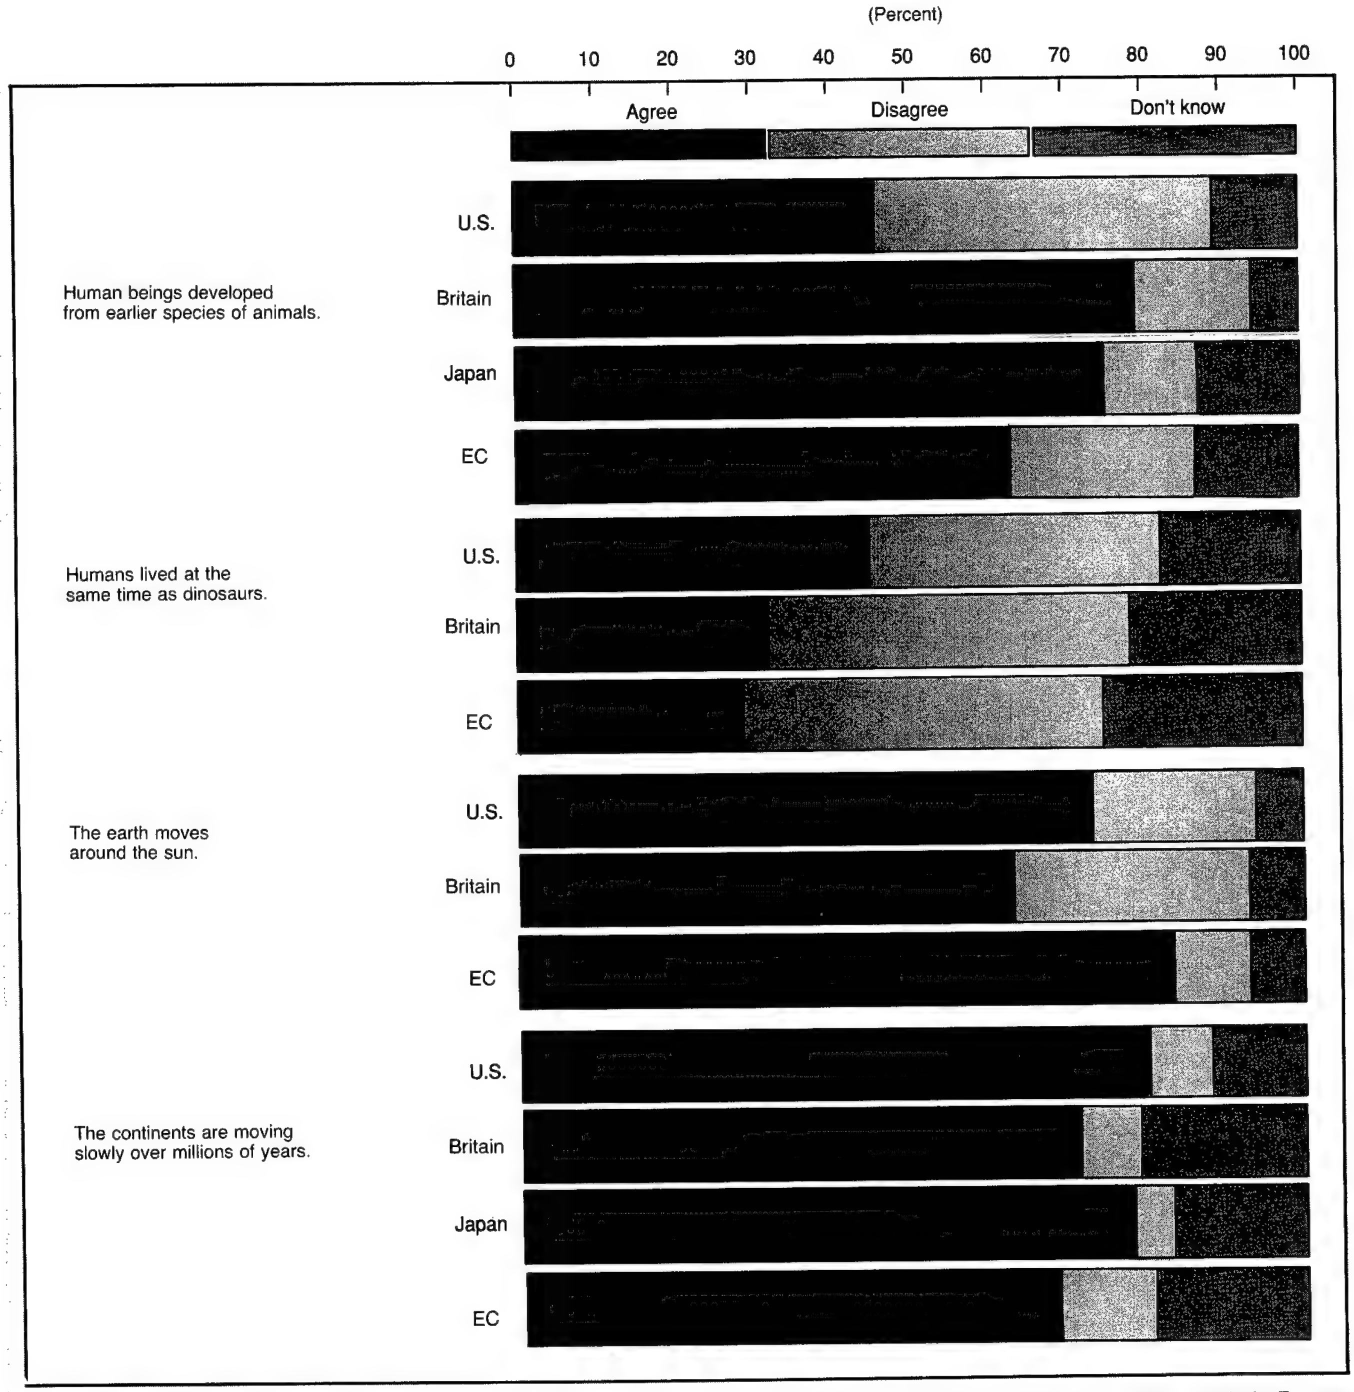
Two weeks after the Challenger accident on January 28, 1986, the individuals in the November 1985 survey sample were resurveyed. While the overall percentage acknowledging that the benefits of scientific research outweigh the harms remained about the same, there was a complete reversal of the percentages holding this view strongly or only slightly. This reversal was maintained when the same sample was questioned a third time in June 1986, after the Rogers Commission had completed its report on the Challenger accident, but also 6 weeks after a second major technological accident had occurred at the Chernobyl nuclear power plant. The results of the three surveys suggested that these technological disasters may have significantly eroded the strongly positive attitudes toward scientific research long held by the U.S. public.

However, a new national sample surveyed 2 years later in July 1988 showed that public attitudes had reverted to their pre-Challenger accident configuration—including both the overall positive assessment as well as the original pattern of the strength of the convictions.

Newly developed internationally coordinated surveys of public attitudes toward S&T are beginning to yield interesting national variations in public perceptions of and knowledge about S&T. Recent national samples of public opinion in the U.S., Britain, Japan, and the European Community (EC) show surprisingly similar patterns of knowledge and ignorance on scientific questions—with one major exception. (See figure O-28.) The British and the EC score a little better than do Americans on the question of the simultaneous existence of humans and dinosaurs; the U.S. and the EC score a little better than Britain on whether the earth moves around the sun. Large majorities in all three countries and the EC give the correct answer on continental drift.

On the issue of the evolution of the human species, however, the U.S. public differs markedly from the other samples. Less than half of the U.S. respondents agreed with the statement about evolution, as compared with 75 percent to 80 percent of the British and Japanese and 62 percent of the EC respondents. The U.S. pattern reflects a history of political and legal controversy on questions of biological evolution rooted in strongly held cultural or religious beliefs.

Figure O-28.
Public knowledge on selected scientific questions, by country



Notes: The U.S. and British data are from surveys conducted in the fall of 1988; the Japanese data are from a survey conducted in the winter of 1985; the European Community (EC) data are from surveys conducted in the 12 EC countries in the spring of 1989. For the precise question wordings, see the appendix tables cited.

See appendix tables 8-3, 8-4, and 8-7, and pp. 165-69.

Science & Engineering Indicators—1989

Chapter 1
Precollege Science and Mathematics Education

CONTENTS

Precollege Science and Mathematics Education

HIGHLIGHTS

Student Achievement

- *Following a wave of school reforms in the early 1980s, test scores on national science achievement tests have shown slight increases during the 1980s.* Achievement trends for 9-, 13-, and 17-year-old students from 1970 to 1986 show a pattern of initial declines followed by subsequent upturns for the three age groups. However, the recent improvements did not offset earlier decreases in test scores, and student scores in 1986 remained below 1970 levels for the three age groups. (See p. 22.)

- *Mathematics achievement showed a similar pattern, with students attaining slightly higher scores on national achievement tests in 1986 than in 1978.* While 9- and 13-year-olds scored slightly higher in 1986 than in 1973, scores for 17-year-olds were slightly lower. (See p. 24.)

- *In both science and mathematics, the largest increases in test scores occurred among the ethnic/racial groups that had performed comparatively poorly in earlier assessments.* For example, 9- and 13-year-old blacks and Hispanics showed larger gains in science test scores than did whites between 1977 and 1986, and the same findings applied to mathematics scores for 9-, 13-, and 17-year-olds between 1978 and 1986. (See pp. 22, 25.)

- *Despite these recent improvements, average black and Hispanic students were still far behind white students in achievement scores in 1986.* In 1986, the average 17-year-old black or Hispanic student performed at the same level as the average 13-year-old white student in the science and math achievement tests; the average 13-year-old black or Hispanic student performed at the average 9-year-old white student level in science. (See pp. 22, 25.)

- *In an international mathematics and science assessment of 13-year-olds conducted in five countries and four Canadian provinces in 1988, U.S. students scored lowest among the 12 populations in mathematics and fourth lowest in science.* South Korean students demonstrated the highest overall mathematics achievement, and British Columbian and South Korean students had the highest science scores. (See pp. 27-28.)

- *In another international science assessment, students at the 5th, 9th, and 12th grade levels in the U.S. performed poorly compared with their counterparts in other countries.* For example, among students taking a particular science course in their final year of high school, of the 13 countries tested, U.S. students placed last in biology, 11th in chemistry, and 9th in physics. (See pp. 28-29.)

Student Coursework

- *Largely as a result of school reform movements, the average number of courses U.S. high school students take in science, mathematics, foreign languages, and computer science has increased proportionally more than it has in other academic subjects.* Students took an average of one semester more of mathematics in 1987 than in 1982, and enrollments in advanced mathematics classes were up by about a third. Course-taking in science was also up, with the percentage of high school students taking a course in biology increasing from 75 percent in 1982 to 90 percent in 1987; increases also occurred in the percentages of students taking chemistry (from 31 percent to 45 percent) and physics (from 14 percent to 20 percent). (See p. 32.)

- *In the international science survey conducted in 1988, U.S. students spent less time on regularly scheduled hands-on activities than did any of the other 12 populations in the assessment.* While U.S. teachers believe that hands-on activity is the most effective method for teaching science, 38 percent of elementary school teachers reported that they use classrooms with no science materials or facilities, and less than half of secondary school teachers said they had access to a general-purpose science laboratory. (See pp. 34-36.)

- *The amount of time spent teaching science and mathematics in elementary school remained the same between 1977 and 1986.* In grades 4-6, science teaching averaged about 30 minutes per day, and mathematics teaching about 50 minutes per day. (See pp. 34-35.)

Teachers and Teaching

- *A 1986 study of the courses that science and mathematics teachers took in college showed that a substantial proportion failed to meet recommended standards for teacher preparation.* Only 34 percent of elementary school teachers who teach science met all of the standards of the National Science Teachers Association (NSTA). An even smaller percentage (22 percent) of grades 7-9 teachers of science met the full standards. At the high school level, 29 percent of biology teachers, 31 percent of chemistry teachers, and 12 percent of physics teachers met all of the NSTA standards. In mathematics, 18 percent of elementary school teachers met all of the National Council of Teachers of Mathematics' recommended standards, while only 14 percent of grades 7-9 teachers, and 15 percent of grades 10-12 teachers, met these standards. (See pp. 37-39.)

- *Among high school math teachers, 29 percent had taken no college math courses in the previous 10 years; the comparable figure for science teachers was 25 percent.* In a national survey conducted in 1986, teachers of science and mathematics said that they typically had spent less than 6 hours in professional development in these subjects during the prior 12 months. (See p. 39.)

A well-educated and trained workforce is essential to maintaining the Nation's domestic progress and world competitiveness, as well as individual progress and prosperity. Nationally, investment in education is one of the important sources of productivity and earnings. For example, recent studies indicate that, in the postwar period, increases in human capital have contributed 10 percent to 20 percent of real economic growth and a similar percentage of the gains in economic productivity. From an individual standpoint, workers with more schooling not only have higher earnings but also safer, more comfortable working conditions and lower rates of unemployment. For example, the unemployment rate for workers with fewer than 4 years of high school is double that of workers who completed 4 years of high school.[1]

The education system can be thought of as a "pipeline" through which students pass, increasing their educational level. Through elementary school and much of secondary school, nearly all students are part of this pipeline. But, as students make decisions about higher education, the pipeline diminishes in size. Particularly important is the period from 6th to 12th grade, when individual students make decisions about which courses to take—and not to take—which areas of the educational curriculum in which to specialize, and which careers to pursue.

As individuals make these plans about their academic future, they are influenced by a number of factors, including family and peer aspirations and motivation, the media, teachers and counselors, and testing practices.[2] Also, the content and quality of elementary and secondary education helps determine individuals' academic preparation for college, their likelihood of graduating from college, and their ability to derive the greatest benefit from a college education.[3]

Because the abilities, attitudes, and aspirations of today's elementary and secondary students directly affect the quality of the Nation's future college-bound population—and ultimately the skill of the Nation's human resources—several prominent and troublesome trends need to be examined:

- Despite recent improvements with respect to some age and ethnic/racial groups, both participation and achievement by U.S. elementary and secondary students in science and mathematics are lagging behind previous years and other countries.

- Participation of women and minorities in science and mathematics, although improving in recent years, still is below the average white male. Achievement of minorities in science and mathematics remains well below that of whites.

- Compared with students in other developed countries, American students demonstrate lower achievement in problem solving and higher-order thinking.

- Many students, particularly those in less affluent schools, are taught by teachers of science and mathematics who are not fully qualified. Shortages of fully qualified elementary and secondary school teachers are most apparent in physics, chemistry, computer science, and mathematics.

In the early 1980s, the widespread nature of these and other problems was drawn to the Nation's attention in a spate of national reports, all of which recommended extensive school reform. More recently, education leaders in all 50 states, as well as numerous local education agencies, have initiated activities to set standards for schools or students.[4] Among the specific problems identified were declining student performance, dilution of graduation standards, and a high school curriculum loaded with electives.

As a result of the numerous commissions and the recommendations contained in their reports, extensive reforms were launched, including, for instance, increasing the number of course credits required to graduate, regulating and standardizing curricula through state frameworks or guides and through the selection of textbooks, and testing for student mastery of basic skills and/or proficiency in subject matter areas.[5] The intent behind this broad range of policy initiatives was to raise student performance and exert some form of quality control over the process of education.[6] And while several national studies discussed in this chapter have shown some overall positive results in student achievement and student course-taking, many states are now in the process of conducting their own studies to evaluate the effectiveness of these reforms.

Structure of the Chapter

This chapter consists of three major parts, organized to discuss the indicators in the categories used by the National Research Council's (NRC) Committee on Indicators of Precollege Science and Mathematics Education.[7] The committee was charged with (1) developing a framework, as far as possible, using existing data to provide a baseline; and (2) suggesting what data and analyses will be needed in the future for a continuing portrayal of the condition of precollege science and mathematics education. The NRC committee defined the concept of an "indicator" as a measure that conveys a general impression of the state or nature of the structure or system being examined. While it is not necessarily a precise statement, it gives sufficient indication of a condition concerning the system of interest to be of use in formulating policy.

To identify the central concepts relevant to the science and mathematics education system, the committee modeled the educational system in terms of *inputs*, *processes*, and *outcomes*. The committee then recommended monitoring the following key schooling variables:

- *Inputs*—teacher quantity and quality, and curriculum content;

- *Processes*—instructional time/course enrollment; and

[1]Council of Economic Advisers (1988), pp. 166 and 170.
[2]OTA (1988a), p. 5.
[3]OTA (1988b), p. 3.
[4]Moyer (1987), p. 1.
[5]Ibid.
[6]Capper (1988).
[7]Raizen and Jones (1985).

• *Outcomes*—student achievement.

The committee considered student achievement to be the primary indicator of the condition of science and mathematics education, since the acquisition of knowledge is the main reason for the existence of formal education. Input and process variables were selected that research had shown to be related to student achievement; namely, exposure to a subject (instructional time/course content), the number and qualifications of teachers with instructional responsibilities in science and mathematics, and the opportunity to learn these subjects as reflected in the content of the curriculum.

This chapter presents most recent data on the above-discussed variables, arranged in accordance with the committee's proposed model of the education system. The chapter also reviews recent educational reform efforts that have been established to improve the quality of student learning, classroom instruction, teacher performance, and curriculum content.

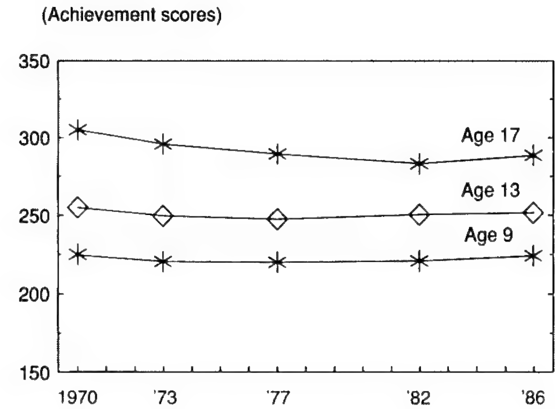
STUDENT ACHIEVEMENT[8]

In the 1985/86 academic year, the National Assessment of Educational Progress (NAEP) tested national samples of 9-, 13-, and 17-year-olds in science, mathematics, and—for the first time—computer competence. These results permit a 17-year trend analysis for five assessments in science (conducted in 1970, 1973, 1977, 1982, and 1986) and a 14-year trend analysis for four assessments in mathematics (performed in 1973, 1978, 1982, and 1986). Also, for the first time, the results in science and mathematics were scaled according to various levels of proficiency.[9]

Science Achievement

While overall trends in science achievement for 9-, 13-, and 17-year-olds across five national assessments from 1970 to 1986 do not reveal dramatic changes, they do show a pattern of initial decline followed by subsequent recovery at all three age levels.[10] (See appendix table 1-1.) These recoveries, however, have not yet compensated for the declines. Declines from the 1970 levels occurred in assessments conducted in 1973 and 1977, but these were followed by upturns in performance between 1982 and 1986. In 1986, however, average achievement at ages 13 and 17 remained below that of 1970; at age 9, average achievement just returned to where it was during the first assessment of 1970. (See figure 1-1.)

Figure 1-1.
National trends in average science achievement: 1970-86



See appendix table 1-1. *Science & Engineering Indicators—1989*

Achievement by Minorities. Despite recent gains, the average achievement of both 13- and 17-year-old black and Hispanic students remains at least 4 years behind that of their white peers. (See figures 1-2, 1-3, and 1-4.) From 1977 to 1986, white students at ages 9 and 13 tended to show slight improvements; black and Hispanic students at these ages showed larger gains. Although all three ethnic/racial groups at age 17 improved from 1982 to 1986, only black students showed important gains across the 9-year span from 1977 to 1986. As a result of recent improvements, 17-year-old black students surpassed their 1977 performance in 1986, while Hispanic and white students did not.

Achievement by Females. At all three ages—but particularly at age 17—the science achievement of females in 1986 was below that of males, a trend that has persisted throughout the 17 years of assessments. The science performance of 9-year-old females in 1986 remained slightly below that of 1970, and the performance gap between males and females at age 9 has increased somewhat during that time. The performance gap between 13-year-old males and females consistently widened across the five assessments. At age 17, although the gap between the sexes continued, trends in performance were comparable for males and females: both groups showed steady declines in performance from 1970 to 1982 and improvements from 1982 to 1986. (See appendix table 1-1.)

Level of Student Proficiency in Science

Based on a review of the NAEP test items by science specialists, the NAEP results were used to describe five levels of student proficiency:[11]

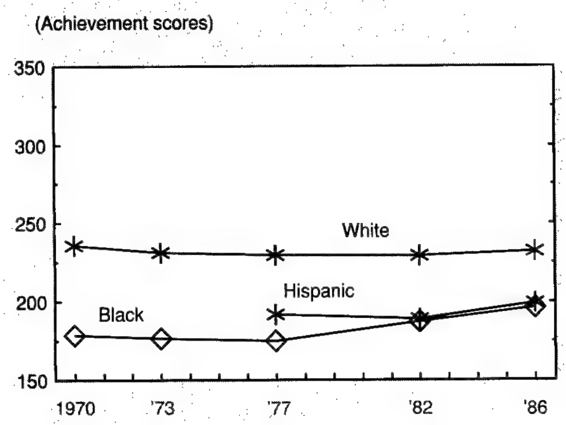
[8]The following information draws heavily on three reports published by the National Assessment of Educational Progress section of the Educational Testing Service under the heading "The Nation's Report Card." See NAEP (1988a), (1988b), and (1988c).

[9]Briefly, the statistical methodology used to develop these proficiency scales involved the computation of percentages of students giving various responses to the assessment items and using Item Response Theory (IRT) technology to estimate levels of science and mathematics achievement for the Nation and for various subpopulations. IRT defines the probability of answering a given item correctly as a mathematical function of proficiency level or skill and certain characteristics of the item. Each proficiency level is defined by describing the types of science and mathematics questions that most students attaining that proficiency level would be able to perform successfully. (See appendix tables 1-2, 1-7, 1-13, and 1-14.) Science and mathematics specialists examined these empirically selected item sets and used their professional judgment to characterize each proficiency level. For a detailed description of the statistical methodology used, see NAEP (1988a) or (1988b), pp. 132 and 141.

[10]NAEP (1988a).

[11]See footnote 9 and appendix table 1-2.

Figure 1-2.
Trends in average science achievement for age 9, by race/ethnicity: 1970-86

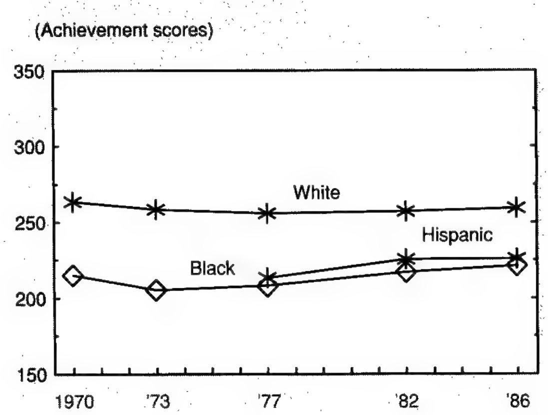


See appendix table 1-1. *Science & Engineering Indicators—1989*

- Knows everyday science facts.
- Understands simple scientific principles.
- Applies basic scientific information.
- Analyzes scientific procedures and data.
- Integrates specialized scientific information.

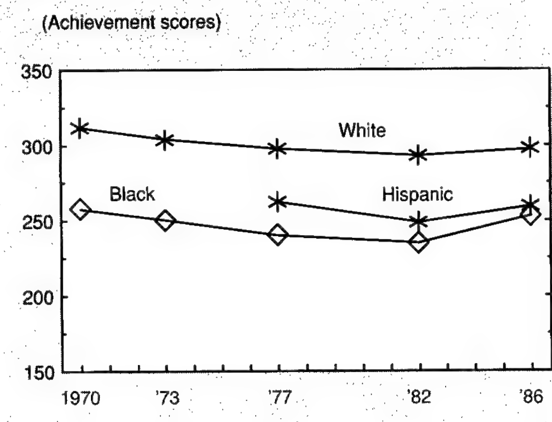
These performance levels can be characterized as the interaction between knowing about science and gaining the ability to perform scientific experiments and using scientific information to infer relationships and draw conclusions.[12] The science specialists who constructed the NAEP items established the level at which students have the ability to analyze scientific procedures and data as characterizing "... the sort of scientific literacy one might expect to be universally held by members of society."[13]

Figure 1-3.
Trends in average science proficiency for age 13, by race/ethnicity: 1970-86



See appendix table 1-1. *Science & Engineering Indicators—1989*

Figure 1-4.
Trends in average science proficiency for age 17, by race/ethnicity: 1970-86



See appendix table 1-1. *Science & Engineering Indicators—1989*

Results of the NAEP analyses of the five levels of student proficiency show that, although recent progress has been made in average student proficiency, most of this has occurred at the lower end of the scale in the areas of basic knowledge and elementary interpretation of scientific information.[14] (See appendix tables 1-3, 1-4, and 1-5.) Approximately 10 percent of junior high school students and only about 40 percent of high school students can be considered moderately versed in science (i.e., able to analyze scientific procedures and data). Only 7.5 percent of the 17-year-olds demonstrated the ability to integrate specialized scientific information. (See text table 1-1.)

By 1986, nearly all students in all three age groups attained a level of scientific knowledge that might be gained from everyday experiences, including elementary

[12]The 1986 NAEP science assessment did not include "hands-on" exercises designed to measure students' ability to "do" science in terms of their ability to use laboratory equipment and apply higher-order thinking skills in experimental situations. The importance of the key types of hands-on exercises was indicated by a recent report of the National Academy of Sciences, which posited that multiple-choice tests are not adequate for assessing conceptual knowledge, most process skills, and the higher-order thinking that scientists, mathematicians, and educators consider most important. Among the types of tests this report advocated were exercises that employ free-response techniques—not only paper and pencil problems but also hands-on science experiments and computer simulations. See Murnane and Raizen (1988), p. 63. Accordingly, the NAEP staff has launched a pilot study of innovative hands-on techniques and exercises to simulate laboratory processes and analytical and interpretative skills needed for problem solving and reasoning of the type used in scientific experiments. See NAEP (1987).

[13]NAEP (1987), p. 48.

[14]See NAEP (1988a), pp. 40-50, for examples of assessment items that typify each level of performance.

Text table 1-1. Percentage of students at or above the five proficiency levels in science, by age: 1977-86

Proficiency level	Age	1977	1982	1986
		Assessment year		
		Percent		
Knows everyday science facts	9	93.6	95.0	96.3
	13	98.6	99.6	99.8
	17	99.8	99.7	99.9
Understands simple scientific principles	9	67.9	70.4	71.4
	13	85.9	89.6	91.8
	17	97.2	95.8	96.7
Applies basic scientific evidence	9	26.2	24.8	27.6
	13	49.2	51.5	53.4
	17	81.8	76.8	80.8
Analyzes scientific procedures and data	9	3.5	2.2	3.4
	13	10.9	9.4	9.4
	17	41.7	37.5	41.4
Integrates specialized scientific information	9	0.0	0.1	0.1
	13	0.7	0.4	0.2
	17	8.5	7.2	7.5

Note: See appendix table 1-2 for definitions of proficiency levels.

See appendix tables 1-1, 1-2, 1-3, 1-4, and 1-5.

Science & Engineering Indicators—1989

facts about the characteristics of animals and the operation of familiar mechanical devices. Also, a significantly greater proportion of both 9- and 13-year-olds demonstrated knowledge of simple scientific principles in 1986 than in 1977. In 1977, 68 percent of the 9-year-olds and 86 percent of the 13-year-olds showed the ability to understand simple scientific principles. Nearly all of the 17-year-olds attained this level in the three latest assessments.

It is of great concern that only about 15 percent of the black and Hispanic 17-year-old students assessed in 1986 demonstrated the ability to analyze scientific procedures and data, compared to nearly half the white students at this age. (See appendix table 1-5.) Of similar concern is that at age 17, roughly half the males, but only a third of the females, were able to analyze scientific procedures and data.

Based on these analyses of levels of proficiency, especially the fact that less than half of all high school students were able to analyze scientific procedures and data, the science educators who assisted in preparing the report concluded that:

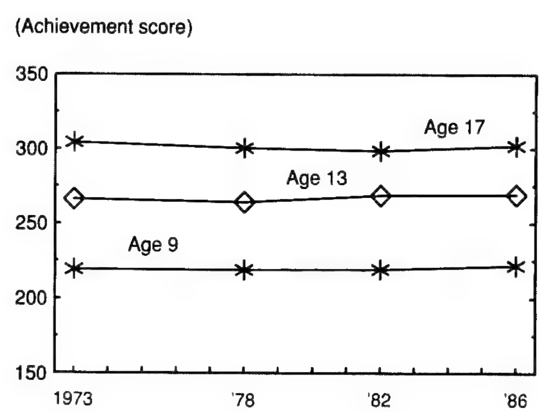
> "In limiting opportunities for true science learning, our Nation is producing a generation of students who lack the intellectual skills necessary to assess the validity of evidence or the logic of arguments, and who are misinformed about the nature of scientific endeavors. The NAEP data support a growing body of literature urging fundamental reforms in science education—reforms in which students learn to use the tools of science to better understand the world that surrounds them."[15]

Mathematics Achievement

Findings from the 1986 mathematics NAEP assessment were similar to those from the science study. Recent mathematics performance has improved somewhat, especially for students at ages 9 and 17. (See appendix table 1-6.) Since 1978, blacks and Hispanics at ages 9, 13, and 17 made appreciable gains. All of these performance improvements, however, have been confined primarily to the lower-level skills. The highest level of performance attained by any substantial proportion of students in 1986 reflects only moderately complex skills and understandings. Most students, even at age 17, do not possess the breadth and depth of mathematics proficiency needed for advanced study in secondary school mathematics.[16]

In the 14-year span covered by NAEP's four mathematics assessments, performance of 9-year-olds was stable between 1973 and 1982 and improved slightly between 1982 and 1986. (See figure 1-5, figure O-13 in Overview, and appendix table 1-6.) Thirteen-year-olds showed some improvement between 1978 and 1986. For 17-year-olds, performance declined slightly from 1973 to 1982, but showed an upturn between 1982 and 1986.

Figure 1-5.
National trends in average mathematics achievement: 1978-86



See appendix table 1-6. *Science & Engineering Indicators—1989*

[15]NAEP (1987), p. 17.
[16]NAEP (1988b).

Achievement by Minorities. At ages 9 and 13, black students have shown steady improvement across the 13-year period from 1973 to 1986; these improvements were most notable from 1978 to 1982 and again from 1982 to 1986. (See figures 1-6, 1-7, and 1-8.) At age 17, black students showed relatively consistent performance between 1973 and 1978, before improving between 1978 and 1986. At age 9, Hispanic students improved slightly with each assessment. At the older ages, Hispanic students showed recent improvements, with the performance of 13-year-olds improving primarily between 1978 and 1982, and that of 17-year-olds improving primarily between 1982 and 1986. Because performance of white students remained at approximately the same level in 1986 as in 1973, while the black and Hispanic scores gained (particularly at age 13), the performance gap between these groups narrowed appreciably.

Factors Behind Changes in Test Scores

A study by the Educational Testing Service (ETS) examined changes in the academic achievement of high school seniors (as measured by various test results, including the NAEP assessments) between 1972 and 1980 and examined the school and student factors related to these changes. (See Rock, et al., 1985.) The findings show that significant shifts in the characteristics of high schools and student behavior were related to test scores. Changes during the period studied at the school and student levels that seem to be most closely associated with lower test scores were:

- A greater likelihood of being in the general or vocational curriculum rather than the academic curriculum;
- A drop in the frequency with which students report taking "traditional" college preparation core courses such as foreign languages, science, and/or courses requiring laboratory work;
- A decrease in the amount of homework done; and
- An increasing dissatisfaction among students with the lack of emphasis on academics in the schools.

This dissatisfaction—shared by students of all socioeconomic statuses (SES) and racial/ethnic groups—was the overall major factor associated with lower test scores. The impact of this shift in emphasis fell primarily on white and upper class students. On the other hand, Federal and state programs designed to strengthen skills in mathematics among low SES blacks appear to have contributed to the test score increase in mathematics among this group.

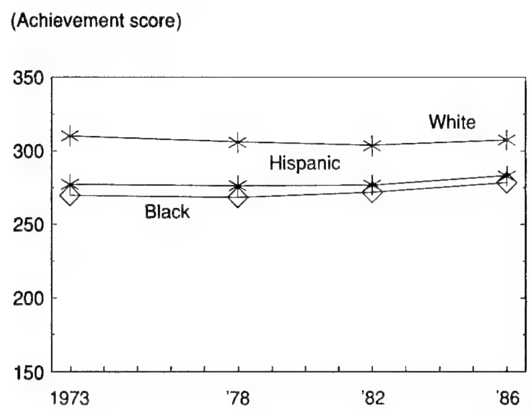
Achievement by Females. Gender differences in mathematics performance were smallest at age 9 and greatest at age 17; in 1986, 17-year-old males scored 5 points higher than females on the proficiency scale. (See appendix table 1-6.) At age 9, females scored higher than males until 1986, when the scores were identical, due to a greater improvement in male scores than female scores between 1982 and 1986. Females at age 13 scored higher than males in the first two assessments; the reverse was true in 1982 and 1986, although both genders showed improved proficiency in 1986 compared with 1973.

Levels of Student Proficiency in Mathematics

As in the science NAEP assessment, five levels of mathematics proficiency were established, in this case by a team of mathematics educators.[17]

[17]See footnote 9 and appendix table 1-7.

Figure 1-8.
Trends in average math achievement for age 17, by race/ethnicity: 1973-86



See appendix table 1-6. *Science & Engineering Indicators—1989*

- Simple arithmetic facts.
- Beginning skills and understanding.
- Basic operations and beginning problem solving.
- Moderately complex procedures and reasoning.
- Multi-step problem solving and algebra.

The performance level associated with "moderately complex procedures and reasoning" represents the level of attainment recommended by the National Science Board (NSB) that all secondary students should achieve, including a variety of mathematical outcomes such as an understanding of the logic behind algebraic manipulations, a knowledge of two- and three-dimensional figures and their properties, and some more advanced objectives.[18]

In 1986, only about half of the 17-year-old age group was able to attain the proficiency level recommended by the NSB. (See text table 1-2.) Moreover, only a small proportion of 17-year-olds (6 percent) showed the ability to do multi-step problem solving and algebra in the 1986 assessment. The percentage of students achieving at this level has remained essentially constant since 1978. This means that few students have, by their last years of high school, mastered the fundamentals needed to perform more advanced mathematical operations.

On a more positive note, in 1986—as in past assessments—virtually all students in all three age groups were able to perform elementary addition and subtraction. There was also some improvement in performing beginning skills and understanding: more 13-year-olds could solve the test items designed to measure basic operations and beginning problem solving in 1986 (73 percent) than in 1978 (65 percent). Most of this gain occurred between 1978 and 1982. (See appendix tables 1-8, 1-9, and 1-10.)

Text table 1-2. Percentage of students at or above the five proficiency levels in mathematics, by age: 1978-86

		Assessment year		
Proficiency level	Age	1978	1982	1986
		Percent		
Simple arithmetic facts	9	96.5	97.2	97.8
	13	99.8	99.9	100.0
	17	100.0	100.0	100.0
Beginning skills and understanding	9	70.3	71.5	73.9
	13	94.5	97.6	98.5
	17	99.8	99.9	99.9
Basic operations and beginning problem solving ..	9	19.4	18.7	20.8
	13	64.9	71.6	73.1
	17	92.1	92.9	96.0
Moderately complex procedures and reasoning ..	9	0.8	0.6	0.6
	13	17.9	17.8	15.9
	17	51.4	48.3	51.1
Multi-step problem solving and algebra	9	0.0	0.0	0.0
	13	0.9	0.5	0.4
	17	7.4	5.4	6.4

Note: See appendix table 1-7 for definitions of proficiency levels.
See appendix tables 1-6, 1-7, 1-8, 1-9, and 1-10.
Science & Engineering Indicators—1989

Among the conclusions reached by the authors of the mathematics assessment was the following:

> "Too many students leave high school without the mathematical understanding that will allow them to participate fully as workers and citizens in contemporary society. As these young people enter universities and businesses, American college faculty and employers must anticipate additional burdens. As long as the supply of adequately prepared precollegiate students remains substandard, it will be difficult for these institutions to assume the dual responsibility of remedial and specialized training; and without highly trained personnel, the United States risks forfeiting its competitive edge in world and domestic markets."[19]

International Assessments of Science and Mathematics Achievement

In recent years, two large-scale international assessments of science and/or mathematics have been conducted. The first was performed in 1988 by the International

[18]NSB (1983), pp. 94-96.

[19]NAEP (1988b), p. 9.

Assessment of Educational Progress (IAEP); it tested 13-year-old students in mathematics and science in five countries and four Canadian provinces.[20] The second assessment, by the International Association for the Evaluation of Educational Achievement (IEA), covered science in 24 countries or systems. The IEA study included students at three levels: age 10, typically grades 4 or 5; 14-year-olds, or grades 8 and 9—the point in secondary school when education in most systems is still full-time and compulsory—and students who were enrolled in science in the terminal year of high school.[21] In the U.S., most students in the 12th grade who are still enrolled in science are taking physics or a second year course in some science.

Both of these assessments point to the same conclusion: U.S. students perform poorly in science and/or mathematics compared with most of their counterparts around the world.

International Assessment of Educational Progress. In the IAEP mathematics assessment, the U.S. ranked last among the five countries and four Canadian provinces.[22] (See figure 1-9 and appendix table 1-11.) Thirteen-year-old students in South Korea had the highest proficiency levels in mathematics—well above the mean—while the other 11 populations clustered themselves into three lower-performing groups.

In the 1988 IAEP science assessment, the U.S. was also among the lowest scoring populations, which included Ireland, French-speaking Ontario, and French-speaking New Brunswick. (See figure 1-10 and appendix table 1-12.) The students of British Columbia and South Korea were by far the highest scorers. The performances of about half the countries were clustered near the mean for all participants.

To make informed judgments about the adequacy of student skills in science and math, the IAEP international tests were scaled at five points similar to the U.S. NAEP science and math assessments.[23] (See appendix tables 1-13 and 1-14.) In mathematics, the results show that South Korean students were much more proficient in solving

[20]In the IAEP study, test items were taken from the 1986 NAEP assessments of science and mathematics.

[21]At the time of preparation of this report, data were available for 15 countries at age 10, 16 countries at age 14, and 14 countries at the terminal year of high school.

[22]Lapointe, Mead, and Phillips (1989).

Science & Engineering Indicators—1989

complex problems than students in most other countries, including the United States. (See appendix table 1-15.) More than three-quarters of the 13-year-old South Korean students could use intermediate mathematical skills to solve two-step problems, compared with only 40 percent of the U.S. students. In terms of understanding measurement and geometry concepts and applying problem solving to more complex mathematical problems, 40 percent of the South Korean, compared with only 9 percent of the U.S., students were successful.

In science, over 70 percent of the 13-year-olds in both British Columbia and South Korea demonstrated the ability to use scientific principles and analyze scientific data, compared with only 42 percent of the American students. (See appendix table 1-16.) Over 30 percent of the students in British Columbia and Korea were successful in solving problems designed to measure the understanding and application of scientific knowledge and principles, compared with less than 12 percent of the students in U.S.

IEA International Science Assessment.[24] In the IEA international science assessment, students in Japan and South Korea (each with average scores of 15.4 out of a possible 24 correct answers to test items) were the top performers among 10-year-olds. U.S. students, along with those from a number of other countries, were in the middle with a mean score of 13.2. The 10-year-old students in the United Kingdom and Hong Kong were among the lowest scorers in the country rankings.

By the intermediate level of schooling, Hungarian, Japanese, and Dutch 14-year-olds demonstrated the highest achievement, correctly answering roughly 20 to 22 of 30 items. U.S. 14-year-old students ranked third to last with an average of about 17 items correct.

At the terminal year of high school, among students who took biology, chemistry, or physics, students in Hong Kong and the United Kingdom were among the highest scorers, with the U.S. students ranking last in biology, third from last in chemistry, and fifth from last in physics. (See figures 1-11, 1-12, and 1-13; and appendix tables 1-17, 1-18, and 1-19.)

Thus, U.S. 10-year-old students in science ranked in the middle of the countries, lost ground by age 14, and scored at or near the bottom by the 12th grade. The opposite pattern is observed in Hong Kong and the United Kingdom, where 10-year-old students score relatively low, but—by the terminal year of high school—move up in the international rankings.

There are several possible explanations for this

[24]In the IEA science study, most of the countries conducted the assessment in 1983. In the U.S., two assessments were conducted, one in 1983 and another in 1986, but the 1983 survey was marked by extremely low response rates and, as a result, these data are not shown here. See International Association for the Evaluation of Educational Achievement (1988), p. 26.

Figure 1-11.

Science & Engineering Indicators—1989

phenomenon. In some countries, notably Hong Kong and the United Kingdom, secondary school students who are skilled in science are provided with the opportunity to study the science curriculum much more intensively than in the United States. Also, in some countries, high achievement is associated with high student attrition rates. Students who do not achieve well drop out early. In Thailand, for example, where scores of 14-year-old students equaled those of U.S. students in the IEA study, only 32 percent of this age group is in school, as opposed to 99 percent of U.S. students. Thus, in-school 14-year-olds in Thailand are a select group of students. On the other hand, however, Japan—a country typically among the highest scoring ones in international assessments of science and mathematics—has a higher student retention rate than does the United States.

Another possible explanation of why the U.S. scores relatively low in international assessments of science and mathematics lies in the type of curriculum studied. Other studies have shown that the science curriculum in the United States is different from that in most other countries. In the United States, most public schools teach one science subject for one academic year and then move on to another discipline the following year; in contrast, the preferred approach in certain other countries is the parallel teaching of an array of disciplines over a period of years.[25] Other speculative explanations include family and community expectations and support.

Computer Competency

Overall, the computer competency assessment found that most students have used computers and have some familiarity with them, but that their competency is generally low and largely restricted to relatively simple computer applications such as word processing. Further, computers are seldom used in subject areas such as mathematics or science, but rather are largely confined to classes about computing and the use of computers.[26]

More than 60 percent of 11th graders correctly identified the word processing functions of "search and replace," "insertion," and "movement of text." (See appendix table 1-20.) At all three grade levels tested, however, students

Science & Engineering Indicators—1989

did not have a clear grasp of graphics functions or the structure and functions of data bases. Only about 10 percent of 7th and 11th graders practiced such applications as often as once a week. About two-thirds of these students had never written computer programs.

White students averaged between 5 and 8 points higher on the computer assessment than did their black and Hispanic counterparts. White students also have a definite advantage over blacks and Hispanics in access to computers at home. Male students have slightly higher computer competency than females, although differences in experience and instruction were small. Families of boys, however, were more likely to own computers: among 11th graders, 35 percent of boys had computers at home, compared with 25 percent of girls.

More than half of grade 3 students have used computers in mathematics classes. But when 7th and 11th grade students were asked how often they used computers in various subject areas, it became clear that computers are primarily confined to the school computer studies curriculum. (See appendix table 1-21.) High percentages of students never use a computer to practice mathematics, science, reading, or other skills from traditional subjects. (See text table 1-3.) Among those who used a computer to practice subject matter skills, only about 5 percent to 10 percent did so more than once a week.

Text table 1-3. Computer use in subject areas, by grade level: 1986

Have you used a computer in any of the following classes?	Grade 3	Grade 7	Grade 11
	Percent		
Mathematics	53.0	39.4	29.1
Reading/English	25.0	23.9	16.9
Science	12.8	11.6	15.4
Social studies	11.7	10.2	4.6

Science & Engineering Indicators—1989

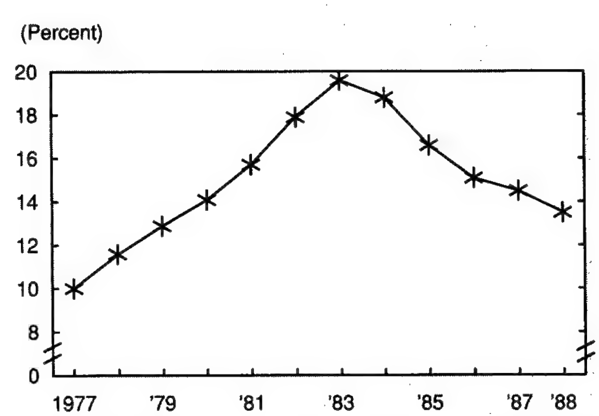
Science and Engineering Interests of College-Bound Seniors

An important indicator of the potential supply of scientists and engineers is the proportion of high school seniors who intend to major in S/E fields in college. Based on the plans of college-bound seniors who take the Scholastic Aptitude Test (SAT), there has been a decline in the proportion of students intending to major in the more quantitative sciences—math and statistics, the physical sciences, engineering, and computer science. (See figure 1-14 and appendix table 1-22.)[27] During the 12-year period from 1977 to 1988, the proportion of college-bound high school seniors who intended to major in these S/E fields doubled, peaking at about 20 percent in 1983, and then gradually declining to about 13 percent in 1988.

Engineering is the most popular of the four quantitative fields; it has held its own since the early 1980s with between 9 percent and 10 percent of college-bound seniors expressing an interest in majoring in it. This represents an increase over the 6 percent of students planning an engineering major in 1977. Interest in computer science dropped from a high of about 7 percent in the early 1980s

Figure 1-14.
Percentage of college-bound seniors intending to major in science and engineering: 1977-88



See appendix table 1-22.

Science & Engineering Indicators—1989

---

[27]Grandy (1989); and ETS (1989).

to less than 3 percent in 1988. Interest in both the physical sciences and math and statistics remained low throughout the 12-year period and has been declining. By 1988, less than 1 percent of the college-bound seniors planned to major in each of these fields.

In 1988, 24 percent of the black males, and 21 percent of white males, intended to major in a quantitative science. Only 11 percent of black females and 5 percent of white females expressed an interest in majoring in these fields. Regardless of race, males were more likely to be interested in the applied engineering subfields than were females.

Academic Persistence of High-Ability Minority Students

Are minority students who test high in ability and express an interest in becoming scientists and engineers more or less likely than whites to persist in preparing for these fields? How do those who persist differ from those who don't? To address these issues, a recent study conducted by the Educational Testing Service sampled 5,000 minority high school seniors who (1) scored 550 or above in mathematics on the SAT, and (2) said they planned to major in math, science, or engineering.

By the spring of 1987 (2 years after taking the SAT), 61 percent of the total sample had enrolled in college and were actually majoring in an S/E field or intended to do so.[28] This proportion greatly exceeds the comparable percentage for the general population of minority students. The persistence rate of high-ability minority students was about twice that of their counterparts in the general population. The comparable persistence rate for high-ability white students was 55 percent.

Those who persisted were different from those who did not in several important aspects. The persisters were much more likely to participate in high school math and science courses and related extracurricular activities. More than half of the persisters had taken high school honors courses in science and mathematics, and two-fifths had taken Advanced Placement (AP) mathematics courses. (See appendix table 1-23.) In this regard, a recent study using High School and Beyond data shows that senior high schools serving predominately poor students typically offer fewer AP courses.[29] Almost two-thirds of high socioeconomic status schools offer AP courses, but less than one-fifth of schools in low-SES communities offer them. Science and math clubs, college-based minority science and engineering recruitment and enrichment programs, and science fair/independent research projects also seem to have been influential in their persistence in science and mathematics studies.

OPPORTUNITIES TO LEARN SCIENCE AND MATHEMATICS

As previously noted (see p. 21), a recent National Research Council report on precollege science and mathematics education recommended that (1) *course enrollments* in secondary school and (2) *instructional time* in the elementary and middle schools be used as key indicators in an integrated system of information about science and mathematics learning. Accordingly, this section deals with these indicators.

Course Enrollments in Secondary Schools[30]

A recent study for the U.S. Department of Education found that long-term patterns of high school course offerings have shifted, particularly in the "general" track.[31] For one thing, the proportion of students in this track dropped from 35 percent in 1982 to 17 percent in 1987; nearly all of this change reflected movement into a more rigorous academic curriculum. As a result, students in 1987 took an average of one semester more of mathematics than they did in 1982, and enrollments in advanced math classes (geometry, second-year algebra, trigonometry, and calculus) were up by about a third. (See appendix table 1-24.) The number of students in pre-calculus had more than doubled, while enrollment in remedial mathematics was down by a third since 1982.

Course-taking in science was also up over the 6-year period. (See appendix table 1-25.) While only 75 percent of 1982 high school graduates had taken a whole year of biology, 90 percent had done so by 1987. The number of students taking a year of chemistry increased from 31 percent to 45 percent. Similarly, the average percentage of graduates taking a full year of physics increased from 14 percent to 20 percent.

Proportionally, there were greater increases in course-taking in science, mathematics, foreign languages, and computer science than in the other academic subjects, reflecting the emphasis in state reform movements on these areas. (See figure 1-15 and appendix table 1-27.) For example, the average high school graduate took 2.2 credits of science in 1982, compared with 2.6 credits in 1987. More time for core curriculum subjects such as science and mathematics was accompanied by relatively small decreases in vocational education programs. In addition,

---

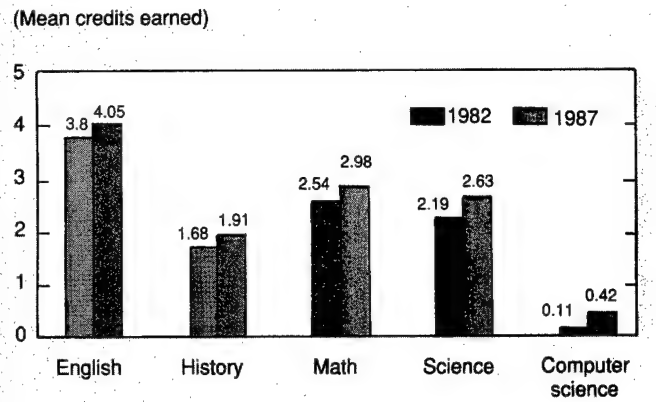
[28]Hilton, et al., (1989), p. 152.

[29]Eckstrom, Goertz, and Rock (1988), p. 50.

[30]An apparent inconsistency is that while student course-taking in secondary math and science has been increasing in recent years, overall student achievement in these subjects has remained relatively static. In this regard, it should be noted that increases in secondary science and mathematics course-taking, as well as the recent increases in some student assessment scores, may portend improvements for the future. Student learning depends on many things besides time spent on a subject. However, the educational reform movements implemented by state and local agencies in the 1980s cannot be expected to have immediate impacts and their full effects may not be seen for some time. In addition, student learning is not only a function of the quantity of time spent on a subject, but also the quality of the curriculum, teacher effectiveness, student interest in particular subjects, availability of adequate laboratories and facilities, and family and community expectations.

[31]In this study, transcripts of 1987 high school graduates were compared with transcripts of 1982 graduates to describe changes in course-taking across this 6-year period. The analyses were based on approximately 15,000 transcripts of 1987 graduates obtained as part of the 1987 High School Transcript Study and 12,000 transcripts of 1982 graduates who participated in the High School and Beyond project. See Westat, Inc., (1988).

Figure 1-15.
Mean number of credits earned by high school graduates: 1982 and 1987



See appendix table 1-27. *Science & Engineering Indicators—1989*

some high schools appear to be lengthening the school day, shortening class periods, and placing less emphasis on noncredit courses such as study hall, gym, and driver's education.[32]

There was a substantial increase in the proportion of high school graduates taking Advanced Placement courses in mathematics and physics. For example, the proportion of graduates taking AP/honors calculus courses increased from 1.5 percent in 1982 to 3.4 percent in 1987; AP/honors physics increased from 1.1 percent to 1.8 percent. Simultaneously, the proportion of students in AP/honors biology decreased from 6.6 percent to 3.0 percent; chemistry essentially held its own (going from 2.9 percent to 3.1 percent). As a result, 66,227 secondary students took the AP mathematics exam in 1988 compared with 31,918 students in 1982. Similar numbers for the AP physics exam were 15,266 in 1988 and 6,804 in 1982.[33]

Course-Taking Trends Among Minorities. There were notable increases in the average number of credit hours taken in mathematics among all racial and ethnic groups. (See figure 1-16 and appendix table 1-26.) The largest increases were shown for Asians, who also took the greatest number of credits in mathematics in both 1982 and 1987.

Course-Taking Trends for Females. The rate of growth for course-taking by female high school students in mathematics was considerably higher than for males, but the average number of credits taken remained higher for males than for females. Females took an average of 2.93 credits in mathematics in 1987, up from 2.46 credits in 1982. Comparable figures for males were 3.04 credits in 1987 and 2.61 credits in mathematics in 1982. The average number of credits taken in science by males and females went up equally—from 2.25 to 2.69 (males), and from 2.13 to 2.57 (females). (See appendix table 1-27.)

Racial, Ethnic, and Socioeconomic Aspects of Opportunities to Learn Science and Math in Secondary Schools

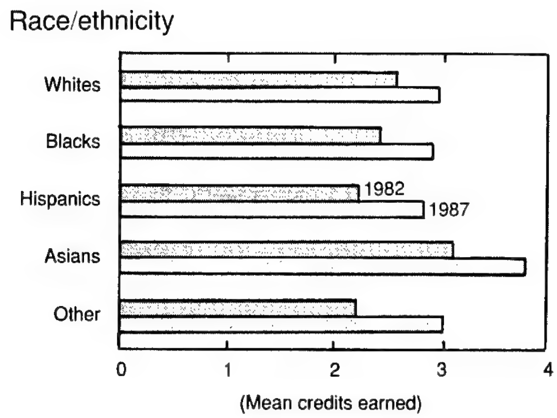
Despite recent gains, the average science and math achievement of 13- and 17-year-old black and Hispanic students remains several years behind that of their white peers. One possible explanation of the relatively poor performance of minority students is that they have fewer opportunities to learn these subjects and that the opportunities they do have are of less quality than those available to white students. To assess this situation with respect to science and mathematics, a recent study by the RAND Corporation attempted to provide a comprehensive set of analyses to determine if and how disparities in school opportunities disadvantage poor and minority students.

Based on preliminary analyses of data from the 1986 National Survey of Science and Mathematics Education (Weiss, 1987), the RAND study showed that a pattern of uneven distribution does exist. For example, based on teachers' reports of their perceptions of the general science and math ability of students enrolled in their classes, students who attend schools with high minority enrollments are far more likely than other students to be enrolled in low-ability science and math classes and far less likely to be in high-ability classes. (See Oakes, et al., n.d.) Student enrollment in classes that teachers perceive to be of "high ability" was only 16 percent in schools where nonwhites comprise more than 90 percent of the school population, while 43 percent were enrolled in "high-ability" classes in schools where white students made up more than 90 percent of the total enrollment. (See appendix table 1-28.)

The same patterns are evident when student ability in science and math is compared with socioeconomic status, as measured by the percentage of students with parents who are unemployed or on welfare and the percentage of students with parents in professional or managerial occupations. As secondary schools become more affluent, they have fewer classes at low-ability levels and more at high-ability levels.

The study authors concluded that poor and minority students are more likely to find themselves in low-ability classes and in courses focused on "general" math and science content. Consequently, students have less access to the topics and curricular objectives that could prepare them for successful participation in academic courses in math and science. On the other hand, whites and students from more affluent families are more likely to be identified as able learners, placed in academic classes, and have greater opportunities to take the critical courses (such as advanced mathematics and calculus) necessary for successful science and math achievement in higher education. In this regard, a recent study comparing course-taking patterns between 1982 and 1987 found that while black high school graduates in 1987 were more likely than in 1982 to study all subjects except calculus, they continued to lag substantially behind white graduates in advanced math courses. (See ETS, 1989, pp. 4-5.) The course-taking patterns for Hispanics generally resembled those of blacks.

Figure 1-16.
Mean number of credits in mathematics earned by high school graduates, by race/ethnicity: 1982 and 1987



See appendix table 1-26. *Science & Engineering Indicators—1989*

Science and Mathematics Instruction in Elementary and Middle Schools[34]

The amount of time spent teaching science and mathematics in elementary schools remained substantially the same between 1977 and 1986. (See appendix table 1-29.) An average of only 18 minutes per day was spent on teaching science in 1986 at grades K-3, compared with around 29 minutes in grades 4-6. Substantially more time was devoted to mathematics at both grade levels. At grades K-3, an average of 43 minutes per day was spent on mathematics in 1986, and around 52 minutes in grades 4-6.

On average, in both 1977 and 1986, elementary school teachers reported spending the greatest amount of classroom time in teaching reading; this was followed by time for mathematics, social studies, and science. (See figure 1-17.)

More specifically, when teachers of third grade students were asked how much time they spent teaching science compared with carrying out other classroom activities during a typical week, half reported spending only 1 to 2 hours each week providing science instruction. About 20 percent of the teachers reported spending less than 1 hour per week teaching science. Only 5 percent reported spending 5 or more hours per week on science. (See appendix table 1-30.)

[34]Recent data on student exposure to science instruction in elementary and middle schools are available from two sources: (1) for all grades at each level in 1977 and 1985-86 from the National Survey of Science and Mathematics Education (Weiss, 1987), and (2) for 1986 at ages 9 and 13 (generally grades 3 and 7) from the science and mathematics assessments conducted by the National Assessment of Educational Progress (NAEP, 1988a and 1988b). In the 1986 National Survey, teachers were asked to report the number of minutes spent in their most recent lesson in a particular subject.

At grade 7, the amount of time spent teaching science still appears to be relatively low, with approximately half of the seventh grade teachers reporting that they devoted 3 hours or less to science instruction each week. Only 14 percent of the teachers reported that they spent 5 hours or more each week teaching science.

Classroom Activities

When teachers were asked as part of the 1986 National Survey to indicate what took place during their most percent lessons in science and mathematics classrooms, they said that most science lessons included lecture and discussion rather than hands-on activities. Use of hands-on activities was more common in elementary school (51 percent of lessons) than in secondary school (43 percent in grades 7-9 and 39 percent in grades 10-12).[35]

Approximately two-thirds of elementary science teachers, and more than three-quarters of secondary teachers, indicated that they believe that laboratory-based activities are more effective than nonlaboratory classroom practices (including lectures). Fewer than 5 percent of the sampled teachers in each group agreed with the statement "Hands-on science experiments are not worth the time and expense." Despite this attitude, experiments conducted in laboratories constitute less than a quarter of the time spent in science classrooms.

At least part of the reason why hands-on science activities are not more prevalent is because many schools lack access to laboratories. In the 1986 National Survey, 38 percent of all elementary teachers surveyed reported that their classrooms have no science materials or facilities. In the 1986 NAEP assessment, slightly less than half of all secondary teachers reported that they had access to a general-purpose laboratory for use in teaching science. (See text table 1-4.) And only one-fifth of the seventh grade teachers had access to more specialized facilities (i.e., a biology or chemistry laboratory).

[35]Weiss (1987), pp. 47-51.

See appendix table 1-29.

Science & Engineering Indicators—1989

Special analyses of the 1986 NAEP data indicate that innovative classroom practices (such as problem solving and conducting experiments in connection with laboratory exercises) are likely to be associated with higher science proficiency. To conduct these analyses, students were asked to report how often they solved problems, conducted experiments alone or with other students, wrote up the results of experiments, read articles on science, and presented oral or written reports. Responses to these questions were ranked as "low," "medium," or "high." Students whose teachers often lectured and seldom engaged the class in experimentation were at the low end of the scale. Those whose teachers used more innovative techniques such as hands-on science experiments and hypothesis testing were ranked at the high end of the scale.

These student-reported types of classroom activities were correlated with actual student achievement scores for the same students. Figure 1-18 shows a positive relationship between science proficiency and innovative instructional activities, even though, as noted above, these practices are relatively rare. The report summarizing the 1986 NAEP data on these questions indicates, however, that it is not possible to determine whether students with greater science proficiency tend to be placed in classes that consist of more innovative curricular activities—or whether these activities yield higher proficiency.[36] The relationship between innovative instructional activities and student proficiency is confounded further by positive correlations between student achievement and a number of other significant factors, including the use of science equipment in the classroom, the ability of the school to instill positive student attitudes toward science, and the beliefs students hold regarding science's applicability in helping remedy human and environmental problems.

Classroom Science and Mathematics Practices in Other Countries. The IAEP international science assessment found that students in the U.S. were the least involved in laboratory experiments and other types of hands-on activities of any of the six countries in the assessment.

In terms of mathematics instruction, however, detailed analyses of eighth grade data from the more extensive 1981-82 Second International Mathematics Study showed that there is a great deal of similarity in teaching practices in the eighth grade around the world. Slightly more than a third of the teachers in that study reported that the majority of class time in mathematics was taken up with the whole class working together as a group, either listening to the teacher lecture or participating in discussions. Teachers in the participating countries reported spending comparatively little time in small group instruction. In all countries studied, more than 75 percent of the teachers reported spending less than 25 percent of their class time in small groups.[37]

Classroom Activities, as Reported by Students. In the 1986 NAEP assessments of science and mathematics, students were asked to report on their teachers' instructional practices and the kinds of learning activities featured in their science and mathematics classrooms. While most science educators encourage the use of hands-on activities, science instruction continues to be dominated by teacher lectures and the reading of textbooks. In fact, the instructional technique reported most often by students was reading science textbooks: over half the students in grades 3, 7, and 11 stated that they read textbooks daily or weekly. Other learning opportunities appear to be neglected. For example, over half the students in third grade said they never went on field trips with their science classes. Of the students in grade 7:

- Over four-fifths never went on science field trips,
- Over half never wrote up the results of experiments,
- About half reported that they never conducted independent science experiments, and
- Nearly half said they never did oral or written reports for science classes. (See appendix table 1-31.)

Among 11th grade students:

- 90 percent reported that they had never done experiments alone, although approximately half reported that they had performed experiments on a weekly basis with other students;
- Slightly more than half reported never doing oral or written reports; and
- Nearly half reported never having gone on field trips or written up results from science experiments. (See appendix table 1-31.)

Similar results were shown for mathematics teaching, where routine instructional approaches predominate.

[37]Burstein (in press).

Use of Calculators and Computers in the Classroom

In the 1986 NAEP mathematics assessment, relatively few students reported having access to *calculators* in school. Only 15 percent of all third graders have calculators for use in mathematics classes and only 21 percent of the seventh grade students and 26 percent of the senior high students used them in mathematics classes at school.

Larger numbers of students reported using *computers* for mathematical purposes, e.g., for learning mathematics through computer instruction, solving mathematical problems, or learning computer programming. Studying aspects of mathematics through computerized instruction seems to peak in junior high school: 39 percent of the 13-year-olds reported having computerized mathematics instruction, compared with only 22 percent of the 17-year-olds. At age 17, access to computers more than doubled between 1978 and 1986; however, most of the increases have occurred in connection with initial high school mathematics courses, such as pre-algebra and algebra I (first year).

Amount of Science and Mathematics Homework

Both the 1986 National Survey and the 1986 NAEP assessment obtained data on time spent on science and mathematics homework. In the National Survey, teachers of science and mathematics were asked to estimate the average amount of time a typical student in a randomly selected class spends on homework during the week. In the NAEP assessment, students in the 7th and 11th grades were asked to report how much time they spent on homework each week.

The findings show that the average amount of time spent on homework in both science and mathematics is relatively small but increases with grade level; also, more time is spent on mathematics homework than on science homework.[38] For instance, almost half of all high school students spend no time (12 percent) or less than 1 hour (36 percent) on science homework per week. Almost two-thirds of all students in the seventh grade spent less than 1 hour each week on science homework.

Analyses based on the 1986 NAEP assessment data show that a reasonably consistent relationship exists between the total amount of homework done and student proficiency in science and mathematics for grade 11 students, but not at the 7th grade. In both mathematics and science for the 11th graders, the more homework, the higher the proficiency. (See appendix table 1-32.) At the junior high school level, no consistent relationship appears to exist between homework and proficiency, although seventh grade students who reported spending no time each week on science homework had the lowest science proficiency.

[38]Despite the relatively small amount of time spent on mathematics homework by most students, reports by 13- and 17-year-olds indicate a dramatic increase in general homework being assigned each day, particularly between 1982 and 1986. In 1982, 73 percent of the 13-year-olds reported being assigned homework in general on a daily basis. This percentage increased to 96 percent in 1986. Results for 17-year-olds were similar, with 70 percent reporting assigned daily homework in 1982, compared to 94 percent in 1986. Data on trends in the amount of time spent on mathematics homework are not available. See NAEP (1988b), p. 107.

INDICATORS OF TEACHING/EDUCATION QUALITY AND QUANTITY

The recent NRC report on precollege science and mathematics indicators pointed out that teacher quality and quantity was a key variable associated with student achievement. This section, accordingly, contains data on college courses teachers have taken as quality indicators. Teacher quantity is explored using data on supply and demand and teacher career patterns.

Teacher Preparation

In recent years, there has been considerable concern that teachers of science and mathematics may be poorly trained and/or inadequately prepared to teach these subjects. For example, a report by the American Association for the Advancement of Science states:

> "Few elementary school teachers have even a rudimentary education in science and mathematics, and many junior and senior high school teachers of science and mathematics do not meet reasonable standards of preparation in those fields."[39]

Furthermore, an NRC report prepared in response to the need to revitalize mathematics and science education, points out that:

> "Too often, elementary teachers take only one course in mathematics, approaching it with trepidation and leaving it with relief. Such experiences leave many elementary teachers totally unprepared to inspire children with confidence in their own mathematical abilities. What is worse, experienced elementary teachers often move up to middle grades (because of imbalance in enrollments) without learning any more mathematics."[40]

To address these issues, a special tabulation was prepared of course-taking data for teachers of science and mathematics. These teacher preparation data—taken from the 1985-86 National Survey of Science and Mathematics Education—were compared with the preservice standards recommended by the National Science Teachers Association (NSTA) and the National Council of Teachers of Mathematics (NCTM).[41]

Elementary School Teachers. NSTA has recommended that elementary teachers have at least one course in each of the three major areas of *science*—biological/life, physical, and earth/space—along with a course devoted to methods of teaching science. While large proportions of the elementary school teachers of science in the 1986 National Survey had taken at least one course in methods of

[39]AAAS (1989), p. 13.
[40]NRC (1989), p. 64.
[41]Weiss (1988a) and (1988b).

teaching science (88 percent), biology (86 percent), the physical sciences (72 percent), and the earth/space sciences (44 percent), only 34 percent meet *all* of NSTA's recommended standards. (See appendix table 1-33.) Five percent of the teachers responsible for instruction of elementary science have had no college coursework in science; another 17 percent have had only one college science course; in most cases, this was a course in biology.

NCTM recommends that elementary teachers of *mathematics* have at least one course each on (1) number systems through the rational numbers; (2) informal geometry including measurement, graphing, geometrical constructions, similarity, and congruence; and (3) methods of teaching mathematics.[42] While nine-tenths of elementary school teachers of mathematics have completed a course in mathematics for elementary school teachers, and an equal percentage have had a course in methods of teaching mathematics, less than one-fifth have completed an appropriate geometry course. (See figure 1-19.) Only 18 percent of elementary school teachers of mathematics meet all of NCTM's recommended standards. (See appendix table 1-34.) At the low end of the scale, 8 percent of these teachers have had no more than one of the three recommended courses.

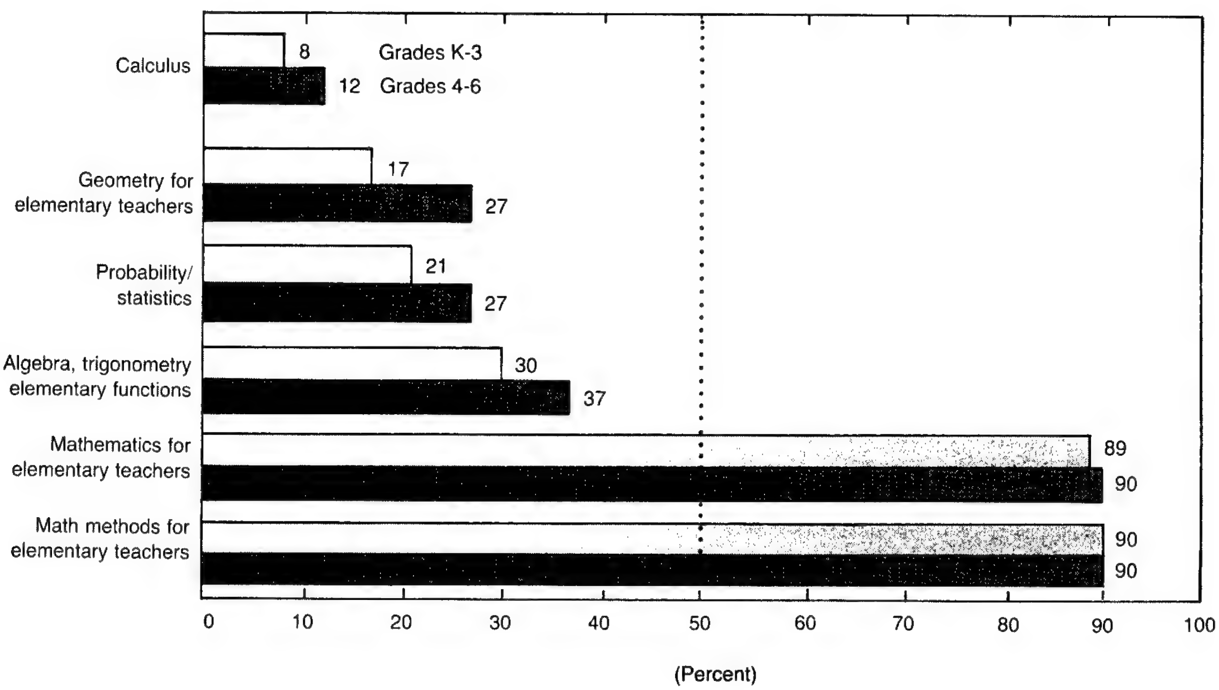
Middle/Junior High School Teachers. NSTA has taken the position that teachers of *science* at the middle school level should be prepared as science generalists rather than as specialists in a particular science discipline. NSTA recommends that these teachers have a minimum of 36 semester credit hours in science, with at least 9 hours each of life, earth, and physical sciences, as well as a course in methods of teaching science. About two-thirds of all teachers of science in grades 7-9 meet the credit hours requirement;[43] however, only 22 percent have the specified distribution of science courses. (See appendix table 1-35.) An additional 2 percent meet the science standards but have not had a course in science teaching methods.

NCTM recommends that middle school teachers of *mathematics* have college coursework in five areas of mathematics (calculus, geometry, abstract algebra/number theory, applications of mathematics, and probability and statistics), computer science using a high-level programming language, and methods of teaching mathematics. Only 14 percent of grades 7-9 teachers of mathematics fully meet these standards. (See appendix table 1-36.)

[42]For the purposes of these analyses, any teacher who has completed a course in mathematics for elementary or middle school teachers, a course in geometry for elementary or middle school teachers, and a course in methods of teaching mathematics is considered to have met these requirements.

[43]Since most science courses are either 3 or 4 credit hours, the 36-hour recommendation by NSTA is roughly equivalent to 11 science courses.

Figure 1-19.
Percentage of elementary teachers who have ever completed selected college courses in math: 1986



SOURCE: Weiss (1988a).

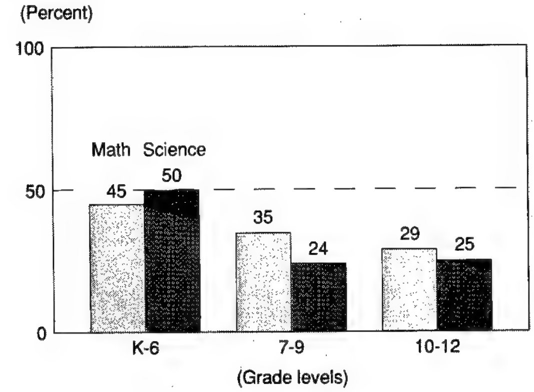
Science & Engineering Indicators—1989

High School Teachers. According to NSTA, secondary *science* teachers should have a minimum of 50 semester credit hours of coursework in science, with at least 32 hours (eight courses) of specifically designated courses in their area of specialty. Although a relatively high number of biology teachers meet the requirement of eight courses, only 29 percent of these teachers meet all of the NSTA recommendations. This is, in most cases, because they lack one or more of the specific biology courses listed. Similarly, less than one-third of the chemistry teachers, and only 12 percent of physics teachers, meet the full NSTA standards. (See appendix table 1-37.)

According to NCTM guidelines, high school *mathematics* teachers should have an extensive math background, including three courses each in calculus, linear algebra, abstract algebra, college geometry, probability and statistics, applications of mathematics, history of mathematics, as well as other upper-level coursework (e.g., applied mathematics from either classical continuous fields or the emerging discrete fields of mathematics). NCTM also recommends coursework in computer programming and methods of teaching mathematics. A total of 54 percent of grades 10-12 mathematics teachers come close to meeting these standards, typically lacking only one or two of the recommended mathematics courses and/or a course in computer programming. However, only 15 percent of secondary school math teachers meet all of the NCTM standards. (See appendix table 1-38.)

Professional Development of Teachers. Based on the inadequacies noted in science and mathematics preparation alone, there is considerable need for additional training of teachers. Moreover, the 1986 National Survey noted that from one-quarter to one-half of teachers had not taken a course in the subject they teach in the 10 years prior to the survey. (See figure 1-20.) Also, while many teachers participate in professional meetings, workshops, and conferences related to the subject they teach, the amount of time they devoted to these professional development activities was typically fewer than 6 hours during the previous 12 months.[44]

Figure 1-20.
Teachers with no college coursework in past 10 years in the subject they teach, by grade level: 1986



SOURCE: Weiss (1988a).

Science & Engineering Indicators—1989

Teacher Supply and Demand

Over the past several years, numerous studies have pointed to a shortage of adequately trained teachers of science and mathematics, predicting that shortages will become worse over time as enrollments rise and the supply of new teachers falls.[45] Educational leaders have tried to respond to these conditions through such measures as differential pay for teachers in shortage areas (including science and mathematics), salary increases for teachers across all fields, and tuition support for teacher training and retraining. For example:

- The Houston school district provided incremental pay for all teachers designated in shortage categories from 1982 to 1987. Mathematics, science, and bilingual teachers were awarded the highest annual increments.
- New mathematics and science teachers were given higher initial salaries in Dade County, Florida.
- Salary contracts in Boston, Detroit, and Hartford contain provisions that allow new teachers in shortage areas to be paid more than their current experience would dictate.[46]

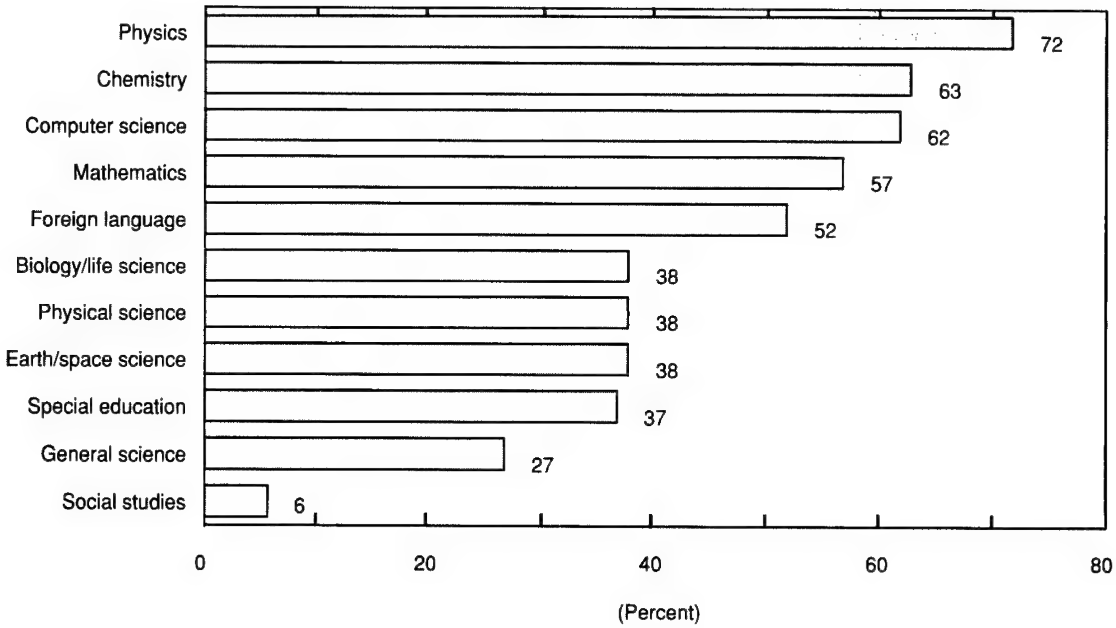
The 1985-86 National Survey of Science and Mathematics Education asked principals to report on the difficulty of hiring qualified high school teachers.[47] The results show that over half the principals in the national sample said that their schools had trouble hiring fully qualified teachers in physics, chemistry, computer science, mathematics, and foreign languages. (See figure 1-21.) Rural high schools were more likely than suburban schools to experience difficulty in recruiting qualified mathematics, biology, earth science, special education, and general science teachers. This difficulty was especially apparent in certain subjects. In biology, for example—which is offered by nearly all high schools—half of the rural school principals said they had difficulty recruiting teachers versus only 13 percent of suburban school principals.

Career Patterns of Teachers, by Teaching Specialty

Until recently, very little has been known about teacher career patterns. How long does the average teacher stay in the teaching profession? How many teachers return to teaching after a career interruption? Do career patterns differ by teaching specialty? Recent research has attempted

[44]Weiss (1987), p. 113.
[45]NRC (1987).
[46]Darling-Hammond (1988).
[47]Weiss (1987).

Figure 1-21.
Percentage of high school principals reporting difficulty hiring qualified teachers, by subject: 1986



SOURCE: Weiss (1987).

Science & Engineering Indicators—1989

to address these questions.[48] In these investigations, the career patterns of beginning teachers were tracked in three states (Michigan, North Carolina, and Colorado) as follows:

- During their initial employment—i.e., the *first spell;* and
- In cases where teachers left the field and returned to a teaching position at a later time, during this second period of employment as a teacher—i.e., the *second spell.*

The research revealed that attrition rates differ significantly for teachers with different subject matter specialties. In Michigan, for example, chemistry and physics teachers were more likely to leave teaching after only a few years in the classroom than were teachers in any other specialty. In fact, only 45 percent of the physics teachers, and 49 percent of the chemistry teachers, were still in the classroom 6 years after they started teaching. In contrast, by the end of 6 years, 61 percent of history teachers and 62 percent of biology teachers were still in the classroom.[49]

In all three states, high school teachers have shorter first-spell lengths than do elementary school teachers. (See appendix table 1-39.) And, among high school teachers, chemistry and physics teachers have shorter average first-spell lengths than teachers of other academic subjects. In both North Carolina and Michigan,[50] the average beginning teacher of chemistry and physics spent less than 5 years in the classroom, versus an average of around 7 years for teachers of social studies and mathematics.

In terms of those who return to teaching after a career interruption, chemistry and physics teachers again have the largest rates of attrition. Only 16.3 percent of the chemistry and physics teachers in North Carolina, and 14.6 percent of those in Michigan, returned to the classroom after initially teaching less than 6 years, compared with 22.6 percent and 22.5 percent, respectively, of the social studies teachers in each state. (See appendix table 1-40.)

Thus, chemistry and physics teachers have the shortest teaching careers. Not only do they leave teaching earlier than do teachers of other subject specialties, they are also less likely to return. This pattern suggests that, because of their higher rates of attrition, teachers of chemistry and physics will be in greater demand than other subject matter teachers in the future. And while teachers returning to the classroom will probably continue to be a significant source of future supply in some areas (e.g., elementary school teaching), they probably will not constitute a major source in chemistry, physics, and mathematics.[51]

EDUCATION REFORM MOVEMENTS

The continuing current high level of Federal and state policy concern with the performance of America's school children in science and mathematics was underscored by the unprecedented and widely publicized "Education

[48]Murnane and Olsen (1989).
[49]Murnane (1987).
[50]Chemistry and physics teachers cannot be distinguished from biology teachers in the Colorado data.
[51]Murnane, Singer, and Willett (1988).

Summit" in September 1989, at which the President met with the governors of 49 states to endorse coordinated policies to improve precollege education.[52] This section highlights the various ongoing initiatives occurring at the state level to improve education quality.

State Reform Movements

During the 1980s, while various prestigious national commissions gathered to study the shortcomings of America's schools and to make recommendations to improve their performance, states also engaged their own review panels. Between early 1982 and mid-1983, states initiated 130 commissions or task forces to look at their own educational practices. By 1984, as many as 290 high-level state commissions were studying the quality of public education. The Education Commission of the States reported that many states had separate commissions working at the behest of the governor, state legislature, and the chief state school officer.[53] Findings, and the proposed and/or implemented solutions these findings have generated, are described in the following paragraphs.

Reforms in Student Preparation. In the area of student preparation, reform activities have been undertaken in setting curricular guidelines and raising curricular requirements for high school graduation and, at the elementary school level, raising the amounts of time devoted to science and mathematics instruction. Also, there is increased concern with assessment of student skills.

Although there is a great deal of variation from state to state, influence is generally exerted over the content of science and mathematics instruction through curricular frameworks, guides, textbook selection, and statewide assessment. Forty-seven states have curricular guidelines in science and mathematics: 27 states have recommended guidelines and 20 have required guidelines.[54]

Forty-six states raised curricular requirements in science and mathematics at the high school level during the 1980s.[55] By 1986, the average number of years of coursework required in science was 1.8 for public schools and 2.5 for private schools; comparable data for mathematics were 1.9 and 2.8 years. For both science and mathematics, the amount of coursework required is still short of the three credits recommended by the National Commission on Excellence in Education. (See figure 1-22.)

At the elementary school level, 25 states have recommended minimal amounts of time that should be devoted to science and mathematics instruction. At the lower elementary level, the range is from 20 to 30 minutes per day;

[52]See *New York Times* (1989).
[53]Kirst (1987).

[54]Moyer (1987), p. 1.
[55]Capper (1988), p. iv.

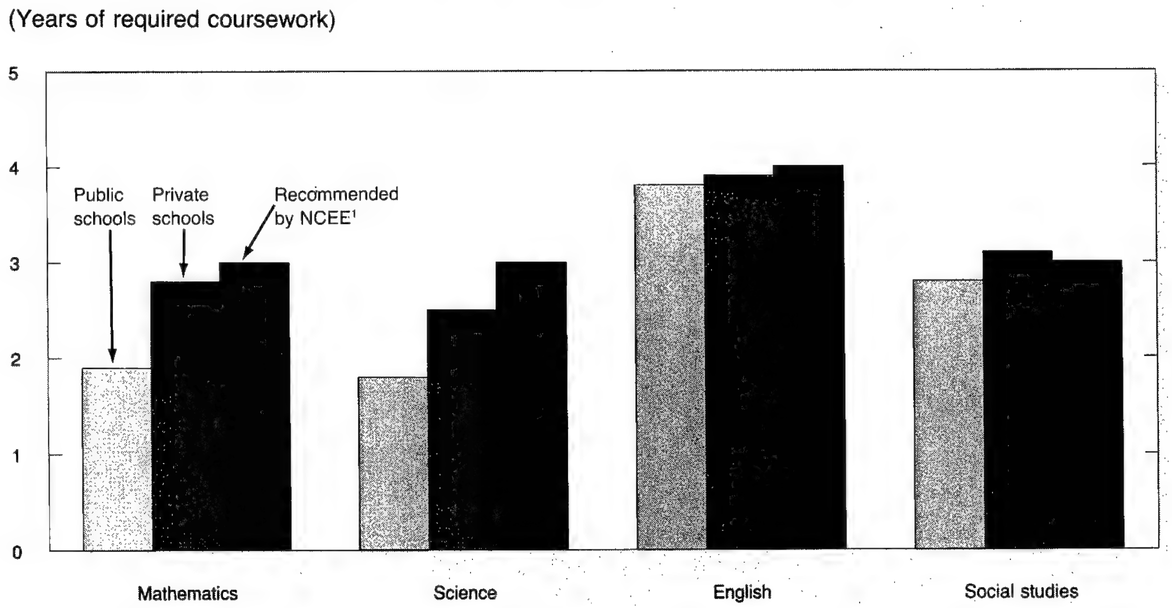
Average years of coursework required for high school graduation, by subject area: 1985-86



[1]National Commission on Excellence in Education.
SOURCE: NCES (1988).

Science & Engineering Indicators—1989

in upper elementary grades, the recommended amount is from 35 to 45 minutes per day. The recommendation for mathematics is approximately 15 minutes per day more at each level.

Almost every state has a statewide testing program of at least one grade level, primarily assessing basic skills of mathematics and reading or language arts. Assessment programs are growing, however, and 30 states now assess students' science knowledge and skills and 43 assess mathematics outcomes.[56]

Reforms in Teachers and Teaching. When asked to identify major problems that their states face in improving science and mathematics instruction, the majority of state-level policymakers point out concerns dealing with teachers and teaching.[57] Thirty states indicate a concern about teachers' understanding of science subject matter content and the ability to teach science so that students—especially young students—will comprehend scientific methodology. One need identified was that "elementary teachers need to more fully understand the use of hands-on, inquiry, and activity approaches in teaching science."

Teacher shortages is another issue of concern among the states—37 states reported a shortage of teachers in terms of either quality or quantity.[58] Other teacher issues included:

- Tendency of teachers to depend heavily on textbooks in teaching science and mathematics,
- Lack of adequate preservice preparation, and
- Lack of funding for staff development and teacher salaries.[59]

Regulation of the amount of science and mathematics course-taking required of prospective teachers varies considerably from state to state. Requirements are particularly low for prospective teachers of elementary grades. Approximately one-quarter of the states have no science or mathematics credit requirements for elementary-level teachers. Most states have course requirements in science or mathematics for middle/junior high school teachers (generally ranging between 12 and 36 semester credit hours in science or mathematics), but an occasional state has none and several leave this decision to the institutions offering certification programs. At the senior high level, almost all states have rather detailed specifications of required science or mathematics course work. One-half of the states do not require that secondary teachers take coursework in methods for teaching science or mathematics.[60]

Higher-order thinking skills (i.e., the ability to infer relationships and draw conclusions and to solve multistep problems) are of particular concern to many educational policymakers, and most states report activity in this area. Some states promote the teaching of higher-order thinking skills through staff development. For example, some states sponsor annual conferences for science and mathematics teachers on incorporating problem solving into their teaching. Some states have held in-service training programs statewide to promote the teaching of these skills, while others include these skills in their assessment programs. In still other states, higher-order thinking skills underlie and are the basis for their curriculum guidelines.[61]

New Institutional Arrangements. Only a handful of states provide sole support for magnet or residential schools that specialize in subject area study. Special schools are more often supported through private organizations or through a combination of resources. Fifteen states report sponsoring, at least in part, schools that focus on science; two more states say that they are considering or proposing a special, science-oriented school. Twelve states report having special schools that focus on mathematics; one state is currently proposing, and another currently developing, such a school. Some states report having more than one special school.[62]

The movement toward administrative and political decentralization of large urban public school systems, such as the Chicago system, will no doubt have a significant impact upon educational practice—including science and mathematics teaching. It is too soon yet to discern the details of the effects.

Impact of State Reforms on Local Schools

For state efforts at improving science and mathematics learning and achievement to be successful, they must be effectively implemented in local educational districts and schools. Two recent projects—one conducted by the Education Commission of the States (ECS), the second by the Center for Policy Research in Education (CPRE)—have studied the effect of state policies on local science and/or mathematics curricula. Study findings are described below.

The ECS project studied the local impact of various state policies designed to improve science curricula—e.g., adoption and improvement of state curriculum guidelines, selection of instructional materials, increased graduation requirements, increased instructional time, higher teacher certification requirements, assessment of student achievement, and evaluation of teaching. The study was conducted in California, Michigan, and Virginia as these states (1) encompass various mixes of policies and (2) form a continuum of state versus local control of education.[63]

The study found considerable evidence of positive impacts of state policy initiatives, but these were not uniform

[56]Ibid., p. v.

[57]Armstrong, et al., (1988), p. 11.

[58]Moyer (1987), p. 12.

[59]Lack of funding was reported by 39 states as a major issue. Half of these states specifically cited lack of funding for materials and updating laboratories as a major problem.

[60]Capper (1988), p. vi.

[61]Moyer (1987), p. 2.

[62]Ibid., p. 5.

[63]Armstrong, et al., (1988). Within each state, researchers interviewed personnel in four school districts as well as in the respective state department of education. They visited three schools in each district, interviewing central office staff, principals, and teachers. These interviews became the basis of case studies and cross-site analyses.

across states or districts. Among the 12 districts studied in depth, classroom impacts were detected in 8. At these sites:

- Increased time and emphasis were given to science instruction—especially in elementary school classes,
- Teachers made increased use of scientific experiments as instructional devices,
- Instructional materials were more available and of higher quality, and
- Instruction was better coordinated among grades.

Impacts were even more apparent at the district level in terms of official curriculum revisions, the content of in-service training sessions, and the adoption of textbooks. In districts where the implementation of state initiatives was successful, the researchers found strong leadership, centralization of curriculum revision, discretionary resources for materials and teacher training, science specialists at the district or school level, and attention paid to monitoring the implementation process.

In some districts (more than half of those in Michigan and Virginia), state science policies were apparently not adopted and consequently had no impact on classroom instruction. On-site visits to four districts in which impacts were generally absent provided a range of explanations, including the existence of unusually high-quality programs prior to the adoption of new state frameworks, a high degree of state autonomy, and rejection of state policies on philosophical grounds.

The CPRE study concentrated on high school graduation requirements.[64] Interview data on the intent and effects of these requirements were gathered in 4 states, 13 districts, and 19 high schools. Comparisons were made of graduation requirements in the core academic subjects of English, mathematics, science, and social studies.

The study findings showed that affluent schools and districts, which typically enroll large numbers of college preparatory students, were relatively unaffected by the reforms, usually because they already had graduation requirements that equaled or exceeded those mandated by the state. This applied to 4 of the 13 districts studied; these all tended to be affluent, suburban, and white.

Where district/school graduation requirements *were* increased, this generally resulted in the addition of mathematics and science courses. Out of 19 schools, 17 reported additions of mathematics and 16 reported additions in science. Moreover—while the ECS study found that hands-on activities were increasing in elementary school classes because of state reforms—the CPRE study found that, at the high school level, the courses added were overwhelmingly of the basic, general, or remedial type. This suggests that the impact of the reform initiatives was largely on middle- and low-achieving students. Of the 17 schools adding mathematics classes, 15 reported additions of basic, remedial, or general courses; this was true of 14 of the 16 schools adding science sections.

Thus, it appears that approximately half a decade after the implementation of a wave of state education reforms, their impact on science and mathematics instruction is yielding mixed results. Change is clearly under way; how far these changes will go, however, remains to be seen.

Chapter 2
Higher Education for Science and Engineering

CONTENTS

Higher Education for Science and Engineering

HIGHLIGHTS

Between 1970 and 1987, institutions of higher education have increased in number and size.

- *Considerable growth was experienced by institutions offering the science and engineering (S/E) degree at some level.* Of the total 650 new institutions, about 400 offered the S/E degree at some level and about 70 awarded the science or engineering Ph.D. The most growth overall (in terms of all degree levels) was experienced in "comprehensive" institutions, which award relatively few S/E Ph.D.s, but considerable numbers of S/E baccalaureates and master's degrees. (See pp. 47-48.)

- *Ph.D.-granting institutions also award relatively high percentages of lower level S/E degrees.* While some 307 institutions offered the Ph.D. in 1986, 95 percent of all S/E Ph.D.s were awarded by 205 institutions. These same 205 also awarded 53 percent of the S/E baccalaureates and 72 percent of the S/E master's. (See p. 48.)

Freshmen continue to display declining interest in some S/E fields.

- *Fewer freshmen plan majors in engineering or computer science.* Between 1982 and 1987, the percentage of freshmen planning undergraduate degrees in engineering fell from 22 percent to 17 percent among men and from 4 percent to 3 percent among women. Both genders combined displayed declining interest in computer science majors, from 4 percent in 1982 to 2 percent in 1987. Interest in the physical sciences as a major has not changed. In contrast to these indicators, freshman full-time enrollments in engineering baccalaureate programs increased in 1988 for the first time in 6 years by about 2,500 students. (See pp. 49-51.)

Graduate S/E enrollments of U.S. citizens have not grown since 1986, while those of foreign citizens continue to increase.

- *In 1987, the long-term trend of increasing graduate enrollments of U.S. citizens in science and engineering programs halted, and these enrollments remained flat in 1988.* Fields experiencing absolute declines in U.S. citizens included engineering and the physical and environmental sciences. (See pp. 52-53.)

- *Enrollment of graduate students from abroad increased in virtually all fields in 1988, continuing a long-term trend.* In engineering, nearly 5 of every 10 students is a non-U.S. citizen, and 4 of 10 in the mathematical and computer sciences are from abroad. Since 1986, the entire increase (about 9,000 students) in graduate enrollments in S/E programs was accounted for by enrollments of non-U.S. citizens. (See p. 53.)

U.S. institutions continue to award more S/E Ph.D.s, especially to foreign citizens and to U.S. women.

- *Total S/E Ph.D.s awarded in 1988 increased by 945 degrees over 1987.* U.S. citizens accounted for one-third of this increase, halting a declining trend over the decade. Engineering showed the strongest gains among U.S. citizens. (See p. 53.)

- *Women U.S. citizens continue to earn increasing proportions of S/E Ph.D.s.* Among U.S. citizens, they earned 32 percent of S/E Ph.D.s in 1988, up from 17 percent in 1975, and were awarded 52 percent of non-S/E Ph.D.s. (See p. 55.)

- *Foreign citizens on temporary visas continue to earn increasing proportions of U.S. S/E Ph.D.s.* Foreigners on temporary visas earned 40 percent of engineering and mathematics Ph.D.s and 24 percent over all S/E fields. (See p. 55.)

Patterns of support for graduate S/E students have changed over the decade.

- *Non-Federal sources of support for graduate S/E study have increased faster than Federal sources.* However, the total number of students reporting mainly Federal assistance in their graduate S/E study in 1988 increased 4 percent over 1987. (See pp. 56-57.)

- *Institutional sources of support have grown most strongly throughout the decade.* In 1988, about 44 percent of graduate S/E students reported institutional support as their main source of support, versus 40 percent in 1980. (See pp. 56-57.)

- *Research assistantships have become the dominant mechanism of support.* Growth in research assistantships as the primary support mechanism has been about 5 percent per year since 1980. This mechanism of support now outnumbers all other support types, including "self-support." (See p. 57.)

More scientists and engineers employed on the Nation's campuses report research as their primary work activity. They are also older and hold higher rank, overall, than earlier in the decade.

- *Increases in "research intensiveness" on the Nation's campuses are evident since 1981.* This increase in research intensiveness, as opposed to teaching, was particularly strong in engineering, where 33 percent of the doctoral

engineers in 1987—versus 23 percent in 1981—reported research as their primary work activity. (See pp. 58-59.)

- *U.S. S/E faculties hold higher ranks and have increased in average age.* The percentage of faculty holding full professorships reached as high as 58 percent in the physical sciences and 55 percent in engineering. These were also the fields with the highest proportions of teaching staff over the age of 50 in 1987, though all S/E fields have experienced declining proportions of younger faculty members since 1977. (See p. 59.)

This chapter discusses indicators of higher learning in science and engineering (S/E). These indicators are grouped into five general topic areas:

- The institutions that offer S/E degrees in the United States, with measures showing how the mix of these institutions has changed over the past few decades and which types of institutions offer S/E degrees at different degree levels and in different S/E fields;
- Information on students in these institutions, including limited data on undergraduate enrollments and plans for an S/E major, and more extensive coverage of graduate enrollments in S/E fields by various student subgroups;
- Recent S/E degrees awarded by these institutions, with trends in Ph.D. awards through 1988;
- Changes in how U.S. S/E graduate students finance their education; and
- Data on faculties in S/E higher education.

For the first time in the *Science & Engineering Indicators* series, the chapter opens the discussion of S/E higher education with an overview of the institutions in which this learning occurs. A recent reclassification of the 3,100 colleges, universities, and specialty schools in the United States permits tracking the changes in their different roles in S/E education since 1970. The distinct educational roles of the various categories of institutions become clear as groups of institutions are compared in terms of the levels and fields of S/E degrees they award.

Undergraduate enrollments in engineering programs and surveys of freshmen as they enter higher education are used as indicators of aspirations and intentions to obtain a science or engineering degree. The chapter then turns to data on S/E graduate enrollments in doctorate-granting institutions.

Degrees in science and engineering fields are indicators of achievement in learning, and these are the subject of the third section. The discussion pays particular attention to Ph.D. attainment among population subgroups and by U.S. citizens as a whole, reflecting ongoing concern of policymakers about these trends. For the first time in this series, this chapter separates out *U.S. citizen* Ph.D. earners by gender and racial/minority groups.

Financial support of students in S/E higher education is an indicator of the value society places on these endeavors, and the different sources and mechanisms of S/E graduate student support are the subject of the following section.

The chapter concludes with indicators of the faculties who teach and guide these students. These indicators concerning the professoriate are largely restricted to its teaching functions and general population characteristics; chapter 5 covers its research activities.

INSTITUTIONS IN S/E HIGHER EDUCATION

The approximately 3,100 institutions of higher education in the United States do not play equal roles in science and engineering education and research.[1] For example, in some fields, degrees awarded at the baccalaureate, master's, and Ph.D. levels are more concentrated in the Ph.D.-granting institutions than in other fields. Also, the number of institutions has expanded over the past two decades, and individual schools have developed into different types of schools as they have increased their program offerings to meet the demands of the growing student population.

A widely used classification of colleges and universities has been developed by the Carnegie Foundation for the Advancement of Teaching (1987).[2] The Carnegie classifications were initiated in 1970 and revised slightly in 1976 and 1987. They thus can be used to track changes over time in the general structure of the U.S. higher educational system as well as in individual institutions, including the relative roles of different institutional types in awarding S/E degrees.[3]

The foundation's classification scheme is based on a combination of factors, including:

- Amount of Federal support,
- Numbers and levels of degrees awarded and numbers of programs awarding such degrees, and
- An index of institutional "selectivity" (for the liberal arts institutions) developed from a number of measures.

Institutional Change Since 1970

Between 1970 and 1987, about 650 new institutions of higher education were established in the United States,

[1]This section focuses on the various educational roles played by these institutions. For discussions of their respective research and development activities, see chapters 4 and 5.

[2]The universe of institutions classified are those canvassed by the Higher Education General Information Survey of the National Center for Education Statistics, U.S. Department of Education.

[3]See Carnegie Foundation for the Advancement of Teaching (1987) for a similar discussion of institutional types broken out by total enrollment trends.

bringing the total to about 3,100 institutions. (See appendix table 2-1.) Of these, approximately 2,400 offer an S/E degree at some level—i.e., from a 2-year (associate) degree to the doctorate.

In discussing the roles of these institutions in awarding S/E degrees and how these roles have evolved since 1970, three aspects of change must be considered:

- Increases in the number of institutions awarding S/E degrees;
- Growth in the total number of institutions, especially at lower degree levels; and
- Expansion of institutions' programs, leading to subsequent reclassification.

During the period 1970-86, the number of institutions awarding the S/E Ph.D. increased by about 70 schools. By 1986, 300 institutions (13 percent) awarded S/E Ph.D.s. Half of this increase was accounted for by "comprehensive" and "other" schools, which offer relatively few Ph.D.s. (See appendix table 2-1.) In addition, the "doctorate-granting" classification grew by 35 universities over the 16 years; this primarily reflected the movement of comprehensive institutions into this category through program expansion and proliferation.

Much larger growth was experienced in the group identified as comprehensive institutions. One-hundred fifty schools were added to this category between 1970 and 1986 in response to several developments in higher education, including:

- Growth and expansion of programs in schools formerly identified as "liberal arts," and
- Growth of large statewide higher educational systems in the 1970s.

Comprehensive colleges may award few doctorates (see appendix table 2-2), but they produce large numbers of S/E baccalaureate and master's degrees.

The number of colleges in the liberal arts category that award S/E degrees has shrunk slightly—from 570 in 1970 to 532 in 1987—largely due to expansion of their programs and subsequent reclassification. This group of schools includes both nationally well-known, highly selective liberal arts colleges as well as a large group of colleges oriented to local industries and continuing education. About 10 percent of these schools offer master's degrees in one or more S/E fields.

The rapid expansion of 2-year colleges offering the associate degree is evident in appendix table 2-1. Over 200 of these colleges offering a technical degree were established between 1970 and 1986, bringing their total to 826 institutions.

"Specialized" schools offering a science or engineering degree doubled in number between 1970 and 1986. Most of these schools are in the health sciences.

S/E Degree Awards in 1986

A cross section of the 1987 Carnegie institutional classification, broken down by numbers and levels of S/E degrees granted in 1986, underlines the different roles of the institutional types in the science and engineering pipeline. Increasingly large proportions of all S/E degrees are granted by the 205 doctoral institutions (though some 307 institutions overall awarded S/E Ph.D.s). These 205 institutions grant almost all (95 percent) of the Ph.D.s, over half (53 percent) of the baccalaureates, and almost three-quarters (72 percent) of the master's degrees in science and engineering. (See appendix table 2-2.) Doctoral institutions also award 7 percent of all S/E associate degrees. Most of these latter, however, are granted by community colleges which, in 1986, awarded 77 percent of these 2-year degrees.

While liberal arts colleges constitute 37 percent of the institutions granting S/E baccalaureate degrees, they awarded only 9 percent of these degrees in 1986. These schools granted 1 percent of the master's and 2 percent of the associate S/E degrees.[4]

Institutional Classification and Degree Field

The roles of different classifications of institutions vary across broad S/E fields. (See appendix table 2-3.) For example, liberal arts colleges award few engineering bachelor's degrees (2 percent of the total in 1986). Engineering degrees at all levels are more often awarded by doctoral institutions, though the comprehensive institutions confer 26 percent of engineering baccalaureates and 13 percent of the master's degrees. (See figure 2-1.) Finally, a small group of specialized institutions award about 6 percent of engineering baccalaureates and 3 percent of the master's degrees.

In contrast to their negligible role in engineering education, liberal arts colleges grant 12 percent of science baccalaureates, reaching 17 percent in the physical sciences and 14 percent in psychology. The comprehensive colleges also grant relatively more science than engineering degrees (37 percent of science bachelor's, and 27 percent of science master's, degrees). Comprehensive institutions also produce relatively high percentages of mathematics and computer science degrees: 44 percent of the combined bachelor's and 29 percent of master's.

THE S/E STUDENT POPULATION

Changing Demographics

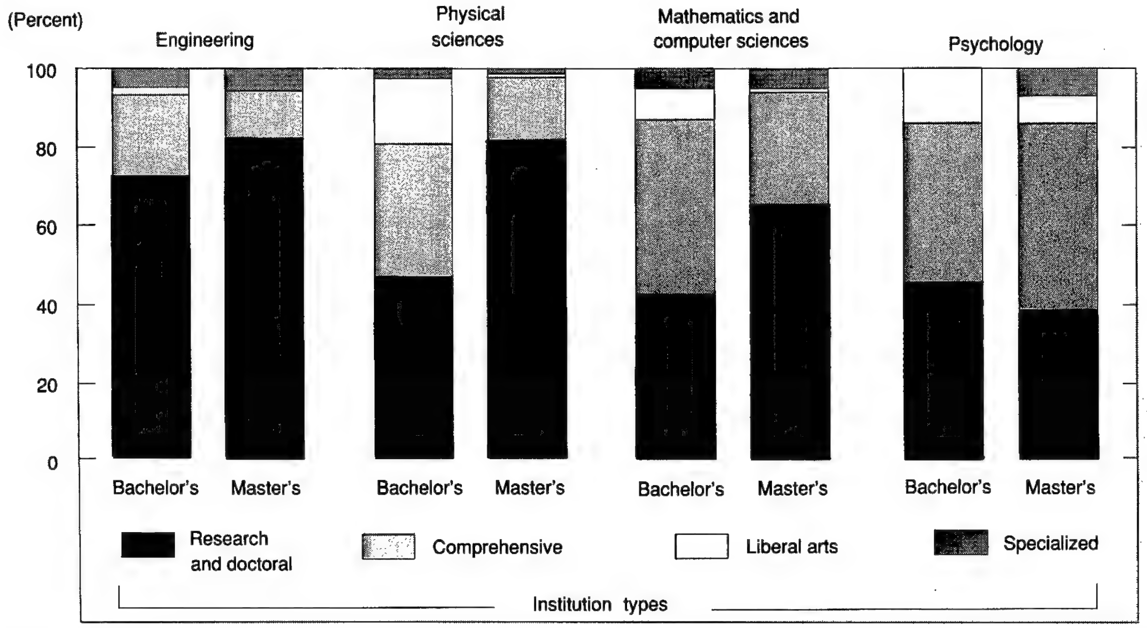
The size of the U.S. population groups normally attending institutions of higher education is declining. For example, 18- to 21-year-olds—the traditional undergraduate student cohort—have been declining in number since 1981. (See appendix table 2-4.)

Decreases in the indicators discussed here may reflect this changing size of the relevant population group; they might also reflect changing choices of individuals. Thus, attention should be paid to changing *rates* as well as to absolute measures.

For example, the data in appendix table 2-4 show that there is not a continuous direct relationship between

[4]See NSB (1987), pp. 47-48, for a discussion of the major role these institutions play in producing baccalaureate recipients who go on to earn S/E Ph.D.s.

Figure 2-1.
S/E bachelor's and master's degrees, by field and institution type



See appendix table 2-3.

Science & Engineering Indicators—1989

demographic trends and enrollment in colleges and universities. Enrollments of 18- to 21-year-olds have not declined as rapidly as the size of that population group; thus, the college-going rate of the group has increased overall.[5] Consequently, the observations in this section are based on trends over time and not on annual fluctuations. These increases, especially among women (both black and white), have helped compensate for the decline in the cohort size to keep enrollments high at U.S. colleges and universities.[6] Also, growing proportions of U.S. high school graduates overall pursue higher education, a trend that has been sustained for at least a decade. (See figure 2-2.)

Indicators for certain population subgroups contrast with the overall trend. Black males aged 18 to 21—after increasing their college enrollment rates by about 5 percentage points from 1980 to 1985—more recently have failed to increase alongside the overall cohort; they may actually have begun to decline. Likewise, attendance rates of 18- to 21-year olds of Hispanic origin show little, if any, increase. (See appendix table 2-4.)

[5]As estimated in the U.S. Bureau of the Census' Current Population Survey (CPS) conducted each October. CPS is a survey of approximately 60,000 households, covering about 125,000 people and 8,000 college students. Some of the detailed categories in these data are necessarily small, and trend data based on them are subject to considerable year-to-year fluctuations.

[6]Significant differences in these trends are likely to exist among individual institutions, across fields, and in various geographic regions.

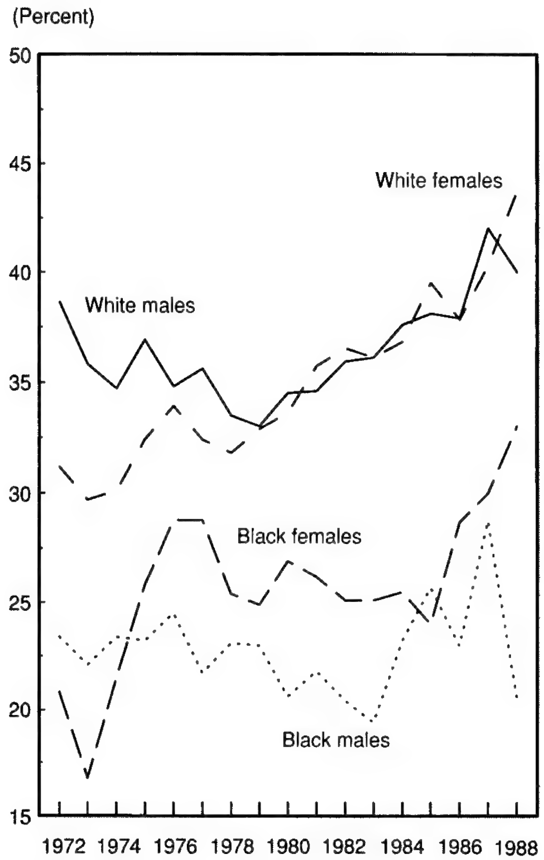
Freshman Plans

Engineering Enrollments. Most undergraduates planning a degree in the sciences need not declare their major field until the second or third year of study. In contrast, the engineering bachelor of science is a 4- or 5-year professional curriculum starting in the freshman year; headcounts of students in these programs provide early indicators of freshman plans. Surveys by the Engineering Manpower Commission provide trend data on the full- and part-time enrollments in both baccalaureate and shorter programs.[7]

In the fall of 1988, approximately 346,000 students were enrolled full time in an engineering baccalaureate program. (See appendix table 2-5.) Freshman full-time enrollments in the 4- and 5-year programs, after decreasing for 5 years, increased in 1988 by about 2,500 students. (See figure 2-3.) Total part-time enrollments in these programs also increased. Since some of these part-time students are midcareer and may be returning to class for specific courses only, it is unclear how many of these students intend to obtain a degree. In 1988, part-time enrollments were 11

[7]American Association of Engineering Societies (1989). The data on engineering programs are from 4- and 5-year programs approved by the Accreditation Board of Engineering and Technology (ABET). Upon successful completion of these programs, the student receives a bachelor of engineering degree or, in the case of the 5-year programs, an engineering professional degree. Engineering technology enrollments, in contrast, are usually in 2-year programs terminating in an associate degree, but some of these programs also include 4-year study. Data on engineering technology enrollments in appendix table 4-5 are from all programs, not just ABET-approved programs.

Figure 2-2.
College attendance rates of 18- to 21-year-olds



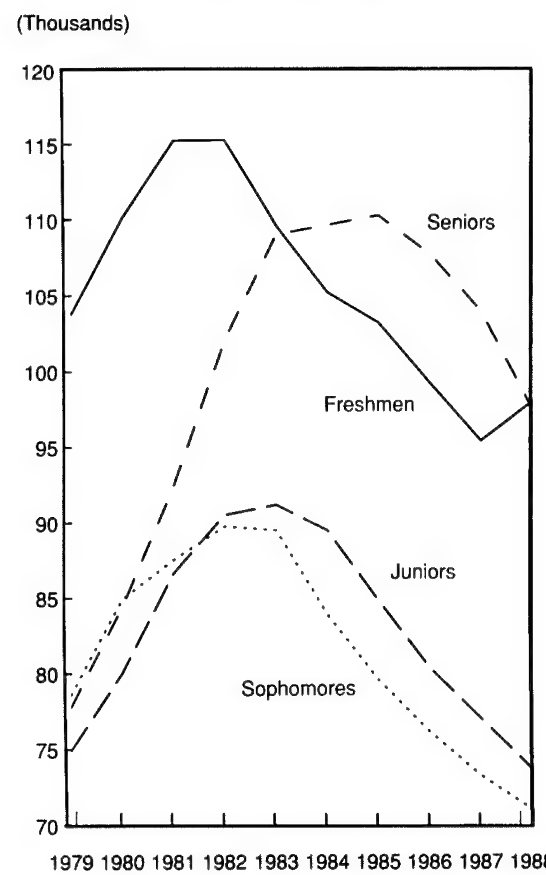
See appendix table 2-4. *Science & Engineering Indicators—1989*

The 1987 Freshman Class.[9] Declining enrollments in engineering are being driven not only by decreases in the size of the 18-year-old population but also apparently by reduced interest in the field among students in successive freshman classes. Between 1982 and 1987, the percentage of freshmen planning a baccalaureate in engineering declined from 12.6 percent to 9.4 percent. (See figure 2-4.) Both male and female interest in engineering majors is falling: among men, from 22.3 percent in 1982 to 17 percent percent of full-time enrollments, and this ratio has hardly changed over the decade.

Enrollments by freshman blacks increased from 5,800 to 6,100 from 1986 to 1987, and total black undergraduate enrollment increased from 16,800 to 17,300.[8] Hispanics, too, increased their freshman enrollment in engineering curricula from 4,300 to 4,500 and from 16,300 to 17,100 overall. Students of Asian origin increased 10 percent among engineering freshmen (to 7,100) and 12 percent overall (to 30,100).

Engineering Technology Enrollments. Full-time enrollments in engineering technology programs—at both the associate and bachelor's levels—declined throughout the 1980s. (See appendix table 2-5.) However, part-time enrollments in these programs have shown recent growth, possibly reflecting increasing midcareer study. The growing number of engineering technology programs (from 200 in 1985 to 310 in 1988) suggests that schools are developing programs to accommodate students who cannot study full time.

Figure 2-3.
Undergraduate engineering enrollments

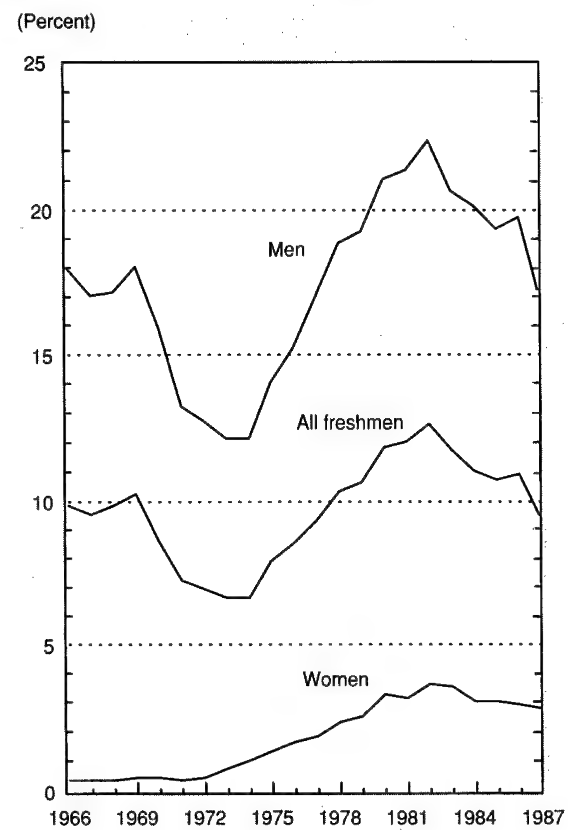


See appendix table 2-5. *Science & Engineering Indicators—1989*

[8]The data in this paragraph are from Ellis (1988).

[9]Data in this section are from the University of California at Los Angeles (UCLA) Cooperative Institutional Research Program, which each fall surveys entering freshmen on various characteristics and their future plans. Excluded from this survey are part-time freshmen and students who have previously attended college for credit. The data also exclude students at semiprofessional and proprietary schools, as well as those at certain very small schools. Data here are from UCLA (1982-87), or—when so cited—special unpublished tabulations. (In the latter case, only freshmen at 4-year colleges and universities are included.) For a complete description of the survey methodology, see any of the UCLA volumes.

Figure 2-4.
Freshman plans to major in engineering



SOURCE: UCLA. *Science & Engineering Indicators—1989*

in 1987, and among women from 3.6 percent to 2.7 percent.[10]

Freshman plans for a major in computer science have also fallen, dropping from 4.4 percent in 1982 to 1.6 percent in 1987 (both genders combined). (See text table 2-1.) Increases in both the biological sciences and social sciences as planned majors have been noted in the UCLA surveys. (See footnote 9.)

In the nonscience fields, business has remained the major of choice for about 25 of every 100 freshmen since 1982; the arts and humanities, however, have increased as a major choice, rising from 8.2 percent in 1982 to 11.3 percent in 1987. Student plans also indicate a trend noted in *Science & Engineering Indicators—1987*:[11] over all fields, more freshmen are planning to study longer and obtain a higher degree. (See text table 2-1.)

When freshmen planning science or engineering degrees are broken down by broad field categories, differences emerge on self-reports of high school grade point averages (GPA), aspirations to the Ph.D., and career plans. (See figure 2-5.)[12] For example, less than one-third of students planning degrees in the environmental, computer, and social sciences report a high school GPA of "A," while

[10]Data on freshman plans for engineering majors from another source, the Admissions Testing Program of the College Board, are reported in Lane (1988).

Science & Engineering Indicators—1989

over half of those anticipating majors in the physical sciences and mathematics report this level of performance. Regarding plans for the Ph.D., 41 percent of freshmen planning baccalaureates in the physical sciences hope to attain the doctorate, as do about one-fourth of freshmen looking to a bachelor's in mathematics or the environmental, biological, or social sciences. In sharp contrast, only about 12 percent of freshmen planning an undergraduate degree in computer science state that they hope to attain the Ph.D.

Depending on their field of interest, freshmen planning S/E degrees differ greatly in their plans for a career as a "research scientist." One-third of freshmen anticipating physical science majors, one-fourth of planned environmental science majors, and one-fifth of planned biological science majors foresee a future as a research scientist (35 percent of the latter plan to enter the medical profession). Three percent of freshmen hoping to attain a bachelor's in mathematics plan to become research scientists, and less than 1 percent in computer and social sciences and in engineering have such plans.

Merit Scholars. Another indicator of freshman plans can be obtained from the stated choice of major of Merit Scholars.[13] While the percentage of scholarship winners who have planned a major in science or engineering has varied over the years, recent trends are downward. (See appendix table 2-6.) Proportions choosing engineering, the sciences overall, and the health sciences are declining; simultaneously, more Merit Scholarship winners are planning majors in the social sciences and humanities. (See figure 2-6.)

Graduate Enrollments[14]

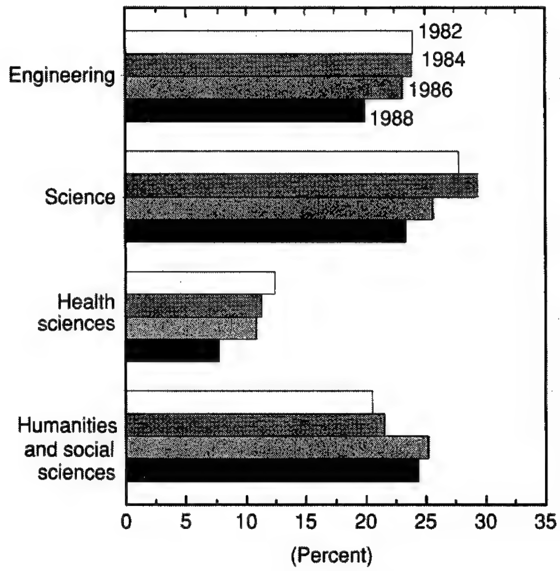
Enrollments of U.S. citizens in graduate science and engineering programs have not increased since 1986. In contrast, students from abroad continued to enroll in these programs in increasing numbers: in 1988, one in four graduate students studying science and engineering in U.S. universities was from abroad.

Other changes are occurring among the graduate S/E student population and the institutions they attend. Decreases in part-time enrollments, and sharp differences in enrollment rates among fields of study, become apparent when overall enrollment data are disaggregated. More women undertake graduate S/E study, and the various racial and ethnic groups display different patterns of

[13] NSB (1977), p. 159. Merit Scholarships are competitive grants administered by the National Merit Scholarship Corporation, Evanston, Illinois. For a complete description of the program, see National Merit Scholarship Corporation (1982-88).

[14] The graduate enrollment data discussed in this section are limited to enrollments in S/E doctorate-granting institutions. These enrollments accounted for 85 percent of all graduate enrollments in 1987 and about 93 percent of total full-time enrollments. For details of the survey universe and student populations, see NSF (1989a).

Figure 2-6.
Choice of major of Merit Scholars



See appendix table 2-6. *Science & Engineering Indicators—1989*

enrollment. These and other trends are discussed in the following paragraphs.

Overall S/E Enrollments. In 1988, total enrollments in all S/E fields combined increased by 1 percent over the previous year, a slowing of the 1980-86 trend of an annual 2-percent increase. (See figure O-15 in Overview.) Virtually all of the 1988 growth in total enrollments was in the sciences; graduate engineering enrollment has remained unchanged for 3 years.

Enrollments by Citizenship. Graduate S/E students who are U.S. citizens increased by 1,300 students in the sciences in 1988, but decreased in engineering by 1,400. (See appendix table 2-8.) Other fields experiencing absolute declines in the number of U.S. citizens enrolled were the environmental sciences (5.6-percent drop)[15] and the physical sciences (0.6 percent).

Foreign enrollments increased in all S/E fields, continuing a trend that has been widely noted and discussed.[16] In full- and part-time study combined, increasing matriculation in science and engineering programs by non-U.S. citizens accounted for the entire growth in enrollments from 1987 to 1988. (See text table 2-2.)

Non-U.S. citizens are attracted to particular fields of study. In 1988, nearly 5 of every 10 full-time engineering students in doctorate-granting institutions were non-U.S. students. (See figure O-16 in Overview.) In the science fields, foreign students made up 37 percent of enrollments in the physical sciences and about 43 percent in both the mathematical and computer sciences.

[15]The environmental sciences in these data include atmospheric sciences, geosciences, and oceanography.

[16]See, for example, NRC (1988b); and NSF (1986).

Text table 2-2. Graduate S/E enrollments by citizenship and enrollment status

	Full-time	Part-time	Total
	—Percent change 1987-88—		
Total enrollment	1.9	-0.2	1.2
Total U.S. citizens	0.3	-0.6	-0.03
Foreign citizens	5.5	2.9	5.2

Note: Includes only doctorate-granting institutions.

See appendix tables 2-8 and 2-9.

Science & Engineering Indicators—1989

Enrollments by Gender. Women have traditionally specialized in the sciences or engineering at rates below those of men. Thus, this large population group has become a focus of attention for policymakers and educators concerned with future supplies of scientific and engineering personnel.[17]

Enrollments of women in graduate S/E programs continued to increase in 1988, and the rate of increase overall is higher than earlier in the decade.[18] By contrast, in engineering, increases averaging 10 percent yearly from 1980 to 1987 slowed to 3 percent in 1988. (See appendix table 2-7.) In both time periods, however, the rates of increase for women exceeded those of men. Women make up about 32 percent of the total graduate S/E enrollment and earn about 32 percent of the doctorate S/E degrees awarded to U.S. citizens.

Like other population groups, women tend to concentrate in certain broad fields. They make up particularly large proportions of total graduate enrollments in psychology (63 percent), the social sciences (47 percent), and the life sciences (41 percent). (See appendix table 2-7.) While they account for smaller proportions in the physical sciences (22 percent), mathematics (29 percent), and engineering (13 percent), their enrollments have been increasing faster in these fields.[19]

Enrollments by Racial/Ethnic Group. The extent to which different population subgroups—e.g., women, some minorities, and older students[20]—choose careers in

[17]For discussions of women at other points in the scientific and engineering pipeline, see the appropriate sections in other chapters of this report. Detailed data are presented in the biennial series *Women and Minorities in Science and Engineering;* for the most recent volume, see NSF (1990). A recent discussion of issues involving women in science and engineering can be found in NSF (1987b).

[18]The statistics discussed in this section obscure the nationality of the men and women described; the questionnaire from which these data are produced does not allow for classifying by gender and nationality. However, because most non-U.S. citizens enrolled in S/E graduate programs are men, the enrollment data for women discussed here may be assumed to include mostly U.S. citizens. Conversely, the enrollment data for men in this section include much of the enrollment by non-U.S. citizens.

[19]In general, graduate S/E fields that attract relatively fewer women than men also tend to be fields with high enrollment of non-U.S. citizens. If the assumption is correct that most of these students are male, then the enrollment rates of females in these fields among students who are *U.S. citizens* could be expected to be higher than identified here.

[20]A recent study of characteristics of students 25 and older is reported in Aslanian and Brickell (1988).

engineering and science has attracted increasing attention. For example, a recent survey of campus administrators reports that many of them perceived their institution's performance in attracting minority students as "fair" or "poor."[21]

About 600 more black U.S. citizens enrolled in graduate S/E programs in doctorate-granting institutions in 1988 over 1987. (See appendix table 2-8.) These increases were spread across all fields, except for a 6-percent decrease in mathematics (about 20 students). Among U.S. citizens in engineering programs, only 1 student in 50 is black.

Enrollments of white U.S. citizens, though relatively unchanged overall, decreased by 3 percent in engineering programs. (See appendix table 2-8.) S/E graduate students of Hispanic origin (U.S. citizens only) have increased their enrollment rates throughout the sciences and engineering in the 1980s; this trend was halted in 1988. Enrollments of U.S. citizens who identify themselves as of Asian background continue to increase in virtually all fields. (See appendix table 2-8.) Overall, the rate of enrollment growth of this population group was 9 percent in 1988. The largest increase for citizens of Asian origin was in the physical sciences (22 percent).

Part-Time Enrollments. *Science & Engineering Indicators—1987* noted strong growth in the number of graduate students in science and engineering who study part time.[22] In 1988, this decade-long trend may have ended. Part-time graduate enrollments in engineering—especially among U.S. citizens—largely accounted for the slowdown.[23] (See appendix table 2-9.)

Enrollments by Field. As noted above, the sciences continued to grow in total graduate enrollments in 1988 over 1987 while engineering enrollments remained unchanged. Among science fields, only the environmental sciences lost enrollment; this continued a 4-year trend in this field. In contrast, the mathematical sciences have experienced strong enrollment growth throughout the decade, especially because of enrollments by non-U.S. citizens. Other fields with strong growth in 1988 were computer science and psychology; both showed a 3-percent increase.

Postdoctoral Appointments[24]

In 1988, about 20,000 researchers held postdoctoral training positions in U.S. research universities. About 1,700 of these were in engineering fields, but this number has been increasing annually by about 8 percent since 1980. (See appendix table 2-10.) In contrast, the number of postdoctorates in scientific fields has grown at an annual rate of about 5 percent over the same period.

Postdoctoral appointments generally grow in conjunction with expanding academic research budgets, and this has been the case throughout the 1980s.[25] In the life sciences, where most (57 percent) of these positions are located, positions increased 11 percent in 1988 over 1987.

Foreign citizens increasingly receive postdoctoral appointments. (See figure 2-7.) Their percentage of all positions in the life sciences increased from 30 percent in 1980 to 42 percent in 1988. In engineering, non-U.S. citizens hold 66 percent of the postdoctoral positions, though this percentage has not changed considerably since 1980. Total postdoctoral appointments held by foreigners have also grown faster than those held by U.S. citizens: about 8 percent versus 3 percent per year, respectively, since 1980.

[21]See El-Khawas (1988).

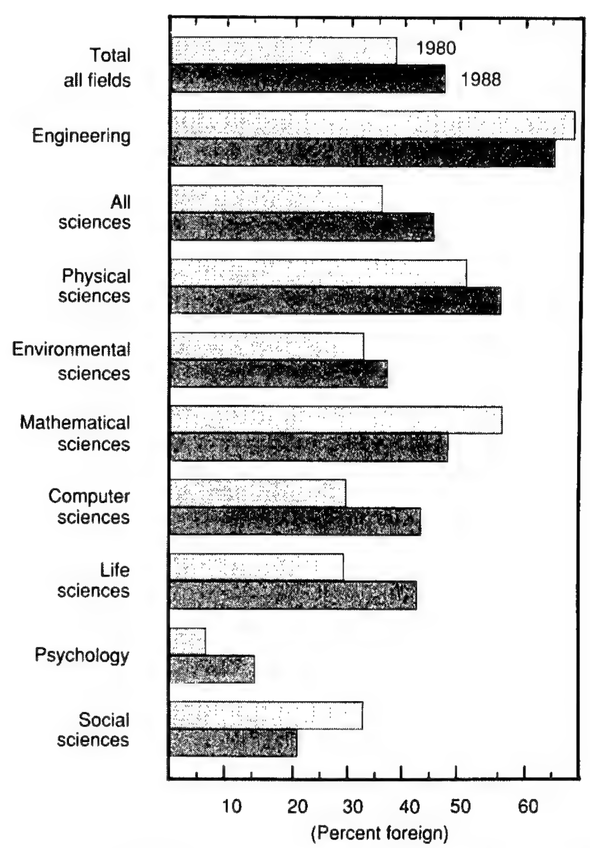
[22]NSB (1987), p. 43.

[23]Relatively few foreign students attend graduate S/E programs part time, largely because of visa regulations.

[24]Data for this section are from NSF, Survey of Graduate Science and Engineering Students and Postdoctorates. Postdoctorates include those individuals with science or engineering Ph.D.s, M.D.s, D.D.S.s, or D.V.M.s (including foreign degrees that are equivalent to U.S. doctorates) who devote *their primary effort* to research activities or study in the department under temporary appointments carrying no academic rank. Such appointments are generally for a *specific time period.* Postdoctorates may contribute to the academic program through seminars, lectures, or by working with graduate students. Clinical fellows, and those with appointments in residency training programs in medical and health professions, are not included unless the primary purpose of the appointment is research training under the supervision of a senior mentor. See NSF (1987), p. 44.

[25]See chapter 4. NRC (1988a) provides detailed data on postdoctorates by fine field.

Figure 2-7.
Foreign S/E postdoctorates, by field: 1980 and 1988



See appendix table 2-10. *Science & Engineering Indicators—1989*

SCIENCE AND ENGINEERING DEGREES

Overall Degree Trends

Ph.D.s in S/E fields accounted for 60 percent of all doctorates awarded in 1988—an increase of 5 percentage points over the past decade. (See appendix table 2-11.)

The total of S/E doctorates awarded by U.S. universities increased in 1988 over 1987 by about 945 degrees. The sciences and engineering each accounted for about half of this increase. (See appendix table 2-12.) Only Ph.D.s in the social sciences and psychology failed to increase.

The last year for which data on bachelor's and master's degrees is available is 1986.[26] Undergraduate awards in science and engineering combined increased from 1985 to 1986 by 2,500 degrees, to a total of about 324,000 degrees. (See appendix table 2-11.) This was 30 percent of all baccalaureates awarded in the U.S., a ratio that has not changed for 3 years. Baccalaureate awards declined in the physical sciences, environmental sciences, and life sciences. Eight hundred fewer students received engineering bachelor's degrees in 1986 than in 1985.

Doctoral Degrees by Citizenship

Following a declining trend for most of the decade, U.S. citizens earned about 300 more Ph.D.s in the sciences and engineering in 1988 than in 1987. (See appendix table 2-14.) Most of these increases were in engineering (220 degrees), continuing a 5-year trend.

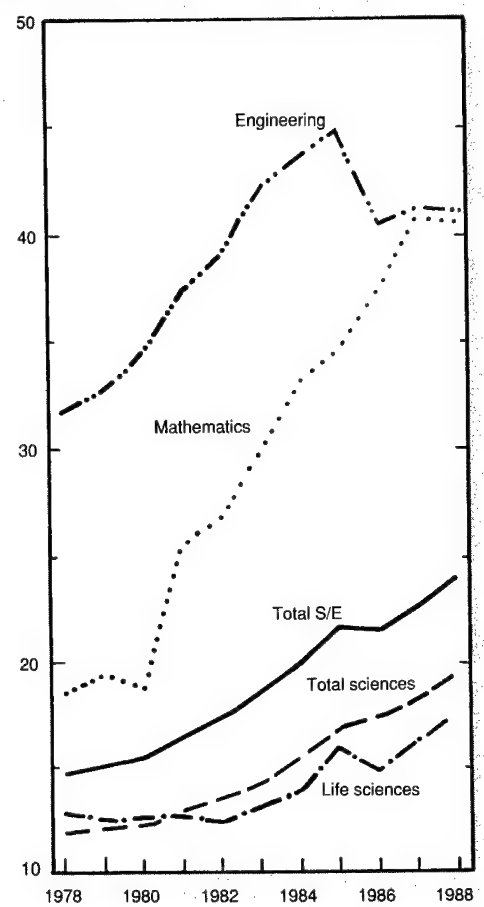
Ph.D.s earned by foreign citizens on temporary student visas account for a growing share of total Ph.D.s awarded by U.S. institutions in most broad science and engineering fields. This phenomenon has attracted widespread attention, leading to speculation about the impacts of this increasing presence of non-U.S. citizens on higher education, future supplies of doctoral scientists and engineers for the U.S. labor market, and the wisdom of relying on immigration of doctoral scientists.[27]

Across the sciences and engineering combined, non-U.S. citizens on temporary visas earned 24 percent of the Ph.D.s in 1988, up from 15 percent a decade ago. (See figure 2-8.) In both the mathematical sciences and engineering, temporary visa-holders earned 40 percent to 41 percent of the Ph.D.s in 1988. Also in that year, non-U.S. citizens earned 25 percent of the Ph.D.s in the social sciences. (See appendix table 2-13.)

Ph.D. Degrees by Gender

The share of total degrees in the sciences and engineering earned by women has remained at about 26 percent for 3 years. (See appendix table 2-11.) Since the majority of the S/E Ph.D. earners from abroad are male, the heavy proportion of non-U.S. citizens in this ratio hides the relative shares of male and female U.S. citizens. When Ph.D.s awarded to foreigners are removed from the total figures,

Figure 2-8.
S/E Ph.D.s awarded to foreigners



Note: Includes only foreigners on temporary visas.

See appendix table 2-13. *Science & Engineering Indicators—1989*

the share of degrees earned by *U.S.* female citizens increases considerably.

In all non-S/E fields, U.S. females earned 52 percent of the Ph.D.s awarded in 1988. (See figure 2-9.) They earned 32 percent of the S/E doctorates awarded to U.S. citizens in 1988, up from only 17 percent in 1975. In 1988, U.S. female citizens earned 10 percent of the engineering doctorates awarded to U.S. citizens and 36 percent of the corresponding science doctorates. However, women are increasing their rates of obtaining the engineering Ph.D. faster than men, about 16 percent per year versus 7 percent per year over the past 4 years. Women's shares of Ph.D.s in both psychology and the life sciences—where they have always been well represented—have increased from 32 percent to 55 percent and from 21 percent to 35 percent, respectively, since 1975. (See appendix table 2-14.)

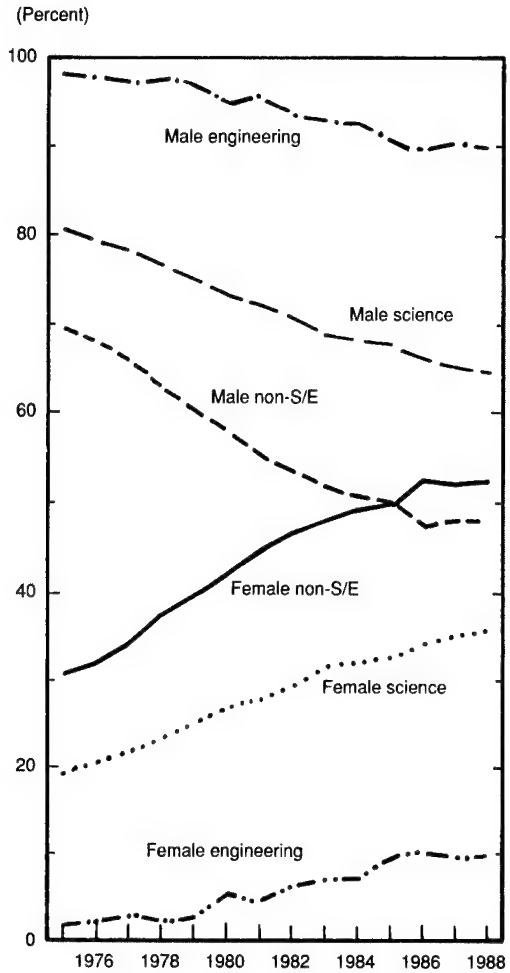
Ph.D.s by Racial/Ethnic Group

Over the past decade, black U.S. citizens have been earning fewer Ph.D.s in science and engineering: in 1988,

[26]For data on degrees using the categories of "job-related" versus degrees in the arts and sciences, see Carpenter (1987).

[27]For example, see NRC (1988b), especially the essays by Drucker, Kuswa, and Luco; and NSF (1986).

Figure 2-9.
Ph.D.s earned by U.S. citizens, by gender



See appendix table 2-14. *Science & Engineering Indicators—1989*

they received 231 such degrees compared with 278 in 1978. (See appendix table 2-15.) Ph.D.s awarded to black female citizens declined in 1988 for the fourth year in a row, though black female citizens earned 390 non-S/E Ph.D.s in 1988 versus 337 in 1987. Black male citizens earned 127 S/E Ph.D.s in 1988. While this was a slight increase over 1987, it was down considerably compared to the late 1970s. In contrast, Ph.D.s earned by Hispanic citizens doubled over the same period, from 160 to 319.

White U.S. citizens earned 299 more Ph.D.s in the sciences and engineering combined in 1988 over 1987. This accounted for almost all of the increase in Ph.D.s earned, and followed 4 years of decline.

U.S. citizens of Asian background, despite their sharp increases in graduate enrollments, earned only 3 percent of the S/E Ph.D.s awarded to U.S. citizens in 1988.

SUPPORT FOR S/E GRADUATE STUDENTS[28]

How do graduate S/E students pay for their educations? Since education is a crucial investment in developing the human talent needed for the Nation's science and engineering activities, the Federal Government has traditionally been a key source of support for graduate S/E study. Institutions, too—using funds in their general institutional budgets—provide support to graduate S/E students in order to attract and retain talented students. Changes in support patterns among mechanisms of student support, and in the different Federal agencies that provide the most graduate S/E student support, are discussed in the following paragraphs.

Sources of Graduate Student Support

One source of information on support of graduate S/E students is an annual survey of graduate S/E departments that requests the "primary" source of support for each full-time student.[29] Four broad categories describe the sources of support for graduate S/E students:

- Federal sources;
- Institutional sources, i.e., funds from schools' general budgets;
- Other sources, i.e., from sources outside the institution other than the Federal Government or the student; and
- Self-support, including the student's own tuition and fees paid.

Institutional sources of support have grown most rapidly throughout the 1980s, averaging nearly 4 percent yearly. In contrast, total enrollment has grown at a rate of around 2 percent per year over the same period. (See appendix table 2-16.) Increased institutional support for S/E graduate students has been particularly important in engineering and the social sciences. For instance, in the social science subfields, expanding institutional support has compensated for a decline in Federal support in these subfields over the decade.

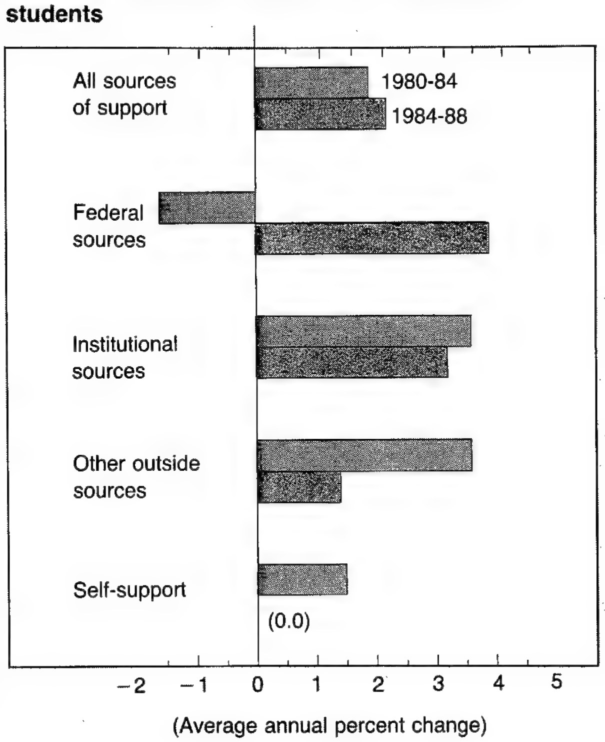
Federal sources of graduate S/E support declined during the first part of the 1980s but turned strongly upward by mid-decade. (See figure 2-10.) In contrast, self-support and other outside sources of support slowed their increases.

Federal support of graduate S/E study between 1984 and 1988 grew most notably among students in computer

[28]This section discusses only full-time students in doctorate-granting institutions.

[29]NSF (1989a). Since students often attend graduate school with a package of financial aid from different sources and of different types, many sources are not reported. Consequently, virtually all support sources are underreported. In addition, no data on the *amount* of support provided are captured by this survey.

Figure 2-10.
Change in sources of support of S/E graduate students



Note: Includes full-time S/E graduate students in doctorate–granting institutions.
See appendix table 2-16. *Science & Engineering Indicators—1989*

science (15 percent annually) and the mathematical sciences (11 percent). Federal sources of support for graduate students in the environmental and social sciences declined throughout the decade. (See appendix table 2-16.)

The net result of these differing growth rates among sources of support for S/E graduate students was a different "mix" of support sources in 1988 versus 1980. By 1988, about 27 percent of S/E students overall reported "self-support" as their main support versus 30 percent in 1980; about 44 percent listed "institutional" support in 1988 versus about 40 percent in 1980; and about 20 percent noted "Federal" sources versus 22 percent in 1980.

Mechanisms of Student Support

Students receive financial assistance for graduate study in the sciences and engineering via five broad mechanisms.[30]

- *Fellowships* are usually awarded through a competition directly to the student by a source other than the institution.
- A *traineeship* is also competitive, but is awarded by the institution.
- *Assistantships* can be either for research or teaching, depending upon how the student's time under the grant is to be spent.
- *"Other"* types of support include Federal student loans and tuitions paid by the Department of Defense (DOD).
- *Self-support* covers student sources including parental support and privately arranged loans.

During the 1980s, the total number of fellowships and traineeships changed hardly at all, in contrast with growth in research assistantships that averaged nearly 5 percent per year. (See appendix table 2-17.) These trends, however, have not been equally distributed among the broad fields. Fellowships and traineeships combined have increased in engineering and the mathematical, computer, biological, and physical sciences. They became less common in all other fields.

Research assistantships have declined only in the agricultural sciences. Fields experiencing considerable growth in the number of S/E students reporting their main source of support as research assistantships include computer science (14 percent annually), engineering (7 percent), and the mathematical sciences (5 percent).

Teaching assistantships increased mostly in the mathematical sciences (4 percent) and engineering (5 percent) since 1980.

Federal Support Patterns

As noted above, Federal sources as a percentage of all sources of support declined between 1980 and 1988. However, the *number* of students reporting Federal sources as their primary support increased by about 4,000 students over the decade. During this period, both the mechanisms of Federal support for graduate students and the relative importance of the various Federal agencies in providing this support have changed.

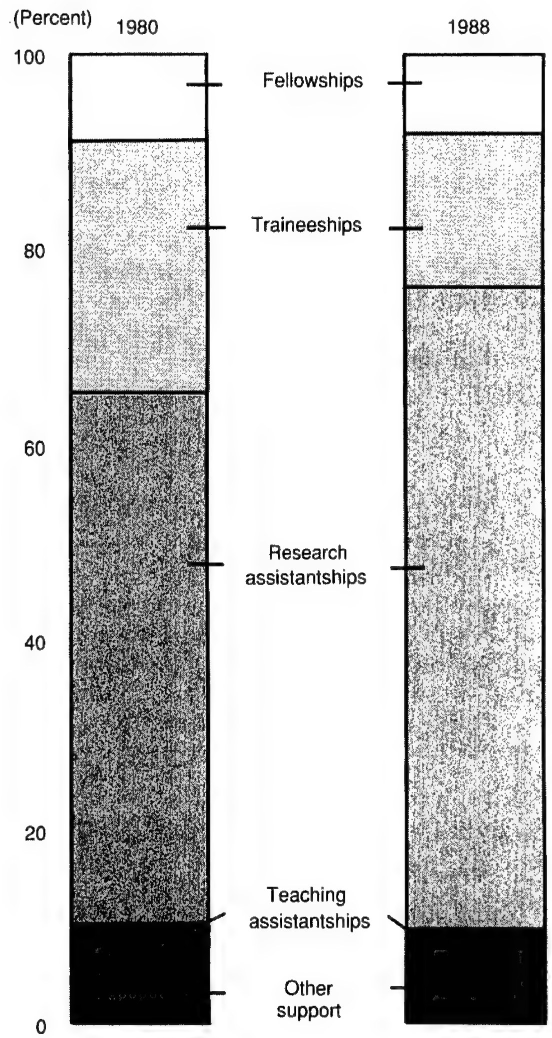
Federally financed traineeships and fellowships have generally declined as a percentage of all Federal support mechanisms since 1980, but the number of research assistantships funded by Federal sources has increased sufficiently to more than offset the declines.[31] (See figure 2-11.) Research assistantships increased among the mechanisms

[30]For precise definitions, see NSF (1987a).

[31]For a detailed statistical study of federally financed research assistantships in science and engineering, see Snyder (1988). Among Snyder's conclusions were:

- "There appears to be a strong relationship between the presence and concentration of federally supported graduate research assistants (RAs) in a department and a variety of measures commonly associated with departmental quality.
- "There are significant differences in the utilization of RAs on research grants (RAs per $ million) by field, with Chemistry having almost 3x the utilization rate as the Biological Sciences.
- "There was a small overall shift in the concentration of federal RA support away from the highest rated (top 10 percent) departments to lesser rated quality departments.
- "The presence of federal RAs appears to have a positive impact on certain outcome measures of graduate education."

Figure 2-11.
Federal support of S/E graduate students, by type of support: 1980 and 1988



See appendix table 2-18. *Science & Engineering Indicators—1989*

of Federal support, rising from 55 percent in 1980 to 66 percent in 1988.

DOD, concomitant with its increased research and development (R&D) funding during the period (see chapter 4), supported 2,900 research assistantships in 1980 and 5,900 in 1988. (See appendix table 2-18.) The National Science Foundation (NSF), which supports the lion's share of research fellowships among the Federal agencies, increased its fellowship programs by about 2 percent per year, from 1,300 to 1,600. The Department of Health and Human Services, which includes the National Institutes of Health (NIH), funded fewer fellowships and traineeships in 1988 than in 1980, despite recent small increases by NIH.

In summary, the growth of federally funded R&D seems to have had the greatest impact on Federal support for graduate S/E students through the proliferation of research assistantships built into Federal R&D grants. Despite recent new NSF programs and slight increases by DOD, federally funded fellowships have not noticeably affected overall Federal support patterns in S/E higher education.

HIGHER EDUCATION S/E FACULTIES

Four-year colleges and universities employ more doctoral scientists and engineers each year. But since recent hiring rates have not kept pace with those of the 1950s and 1960s, these scientists and engineers are relatively older—and hold higher ranks—than a decade ago. Moreover, in recent years, increasing proportions of scientists and engineers in academic settings report greater amounts of work in research and development, suggesting a growing "research intensiveness" of U.S. college and university campuses. There are, however, differences among broad S/E fields for each of these general trends, as discussed in the following paragraphs.

Overall Employment Trends

U.S. colleges and universities[32] employed approximately 186,000 doctoral scientists in 1987—or 53 percent of the total doctoral scientists employed in the U.S.—and 24,000 doctoral engineers, or 35 percent of the Nation's employed doctoral engineers. (See appendix table 2-19.) The number of doctoral engineers on U.S. campuses has increased at twice the rate of doctoral scientists: 10 percent per year versus 5 percent per year, on the average, since 1981.

Patterns of Academic Employment

The percentage of academic doctoral scientists and engineers who report teaching as either their primary or secondary work activity has not changed considerably over the years. (See appendix tables 2-20 and 2-21.) However, some fields have considerably more doctoral staff on campus who perform research or other tasks to the exclusion of teaching. Up to 90 percent of mathematical Ph.D.s, for example, report teaching as a major work activity; in contrast, in the life sciences, only 60 percent to 65 percent have teaching duties. Computer science and the physical sciences also have relatively large proportions of Ph.D.s on campus who do not teach.

A growing research intensiveness of the Nation's campuses is further suggested in appendix table 2-20. Between 1981 and 1987, across nearly all fields, increasing proportions of academic doctoral scientists and engineers identified research and development as their primary work activity, while declining proportions identified teaching as their primary work activity. This general trend seems stronger in engineering than in the sciences: among doctoral engineers, the percentage reporting R&D as their primary activity rose from 23 percent in 1981 to 33 percent in 1987; corresponding growth among scientists was from 29 percent to 35 percent.

[32]The discussion throughout this section refers only to employment at 4-year colleges and universities.

Text table 2-3. Academic doctoral scientists and engineers, by age and field

	Percentage under 40					Percentage 50 or older				
	1977	1981	1983	1985	1987	1977	1981	1983	1985	1987
All scientists and engineers	45	38	33	32	29	26	30	32	32	34
Scientists	45	39	34	32	29	26	29	32	32	33
Physical scientists	46	34	27	28	25	24	32	34	35	39
Mathematical scientists	53	38	30	28	29	19	24	27	32	32
Computer scientists	57	48	48	41	31	15	20	20	19	21
Environmental scientists	45	36	37	32	30	24	26	31	33	33

Social scientists	40	35	31	28	25	30	34	35	34	34
All engineers	38	29	28	30	27	26	34	34	37	41

See appendix table 2-19.

Science & Engineering Indicators—1989

Most of the increase in R&D has been focused on applied, rather than basic, research. In both science and engineering, doctoral employees report more work in applied and relatively less work in basic research. (See appendix table 2-20.) Moreover, since 1981, the number of academically employed doctoral scientists and engineers who report basic research as their primary activity has grown by 28 percent, compared with a 75-percent growth in reports of applied research.

Only the mathematical and computer sciences go against these general trends, however. In the mathematical sciences, the increasing percentage of doctoral scientists reporting R&D clearly emphasizes basic over applied research (81 percent in 1981 to 89 percent in 1987, versus 16 percent to 11 percent, respectively). In computer science, the recent high rates of growth in total employment in colleges and universities have left the percentage of total employment engaged primarily in either teaching or research virtually unchanged. Also, the percentages reporting either basic or applied research as a primary activity both increased at the expense of those researchers who reported development work in earlier surveys. (See appendix table 2-20.)

Academic Rank and Age

Engineering and most broad science fields have experienced increases in senior faculty ranks since 1981.[33] In engineering, the percentage of the professoriate holding the rank of full professor has grown to 55 percent in 1987, an average annual rate of growth of 5 percent since 1981. (See appendix table 2-21.) Among the sciences, the physical and mathematical sciences stand out with high percentages of faculty who are full professors: 58 percent and 50 percent, respectively. Concomitantly, the ranks of assistant professors have decreased in these fields; the use of instructors has decreased in all fields.

As a relatively new discipline, computer science has retained an anomalous position in the face of these general trends.[34] Compared with all other broad fields, computer science has more faculty with lower rank—e.g., 38 percent associate professors and 29 percent assistant professors versus 28 percent and 19 percent, respectively, in all S/E fields combined.

On average, academically employed doctoral engineers and scientists were older in 1987 than in 1977. (See text table 2-3.) In all fields, decreasing percentages were under 40 years of age in 1987 than in 1977, and increasing proportions were over 50. In engineering, a recent upturn in the proportions under 30 may have ended in 1987. (See appendix table 2-19.) Finally, in all fields, the proportions of doctorates employed in colleges and universities who are over 60 years of age increased considerably since 1977, and more than doubled (for example) in engineering and computer science.[35]

[33]This and the next paragraph discuss only academic doctoral scientists and engineers who teach—i.e., "the professoriate"—as opposed to the total academic doctoral S/E employment discussed in the preceding paragraphs.

[34]NSB (1987), p. 49.

[35]For a discussion of possible future faculty shortages, see Lozier and Dooris (1987). In El-Khawas (1988), campus administrators reported shortages of faculty in computer science and an inability to fill vacancies in mathematics.

Chapter 3
Science and Engineering Workforce

CONTENTS

Science and Engineering Workforce

HIGHLIGHTS

- *Between 1980 and 1988, the number of those employed in science and engineering (S/E) jobs in private industry increased at a rate almost twice that for all workers.* Concurrently, the occupational and industrial mix of S/E employment experienced major changes. (See p. 63.)
- *Approximately 2.0 million scientists and 2.6 million engineers were employed in the S/E workforce in 1988.* Science employment nearly doubled since 1980, while employment of engineers increased by almost 75 percent. (See p. 66.)
- *Almost one-fourth of all scientists and one-tenth of all engineers employed in the United States in 1988 were working in non-S/E activities.* Within science fields, social scientists and computer specialists were the most likely to report non-S/E employment, while mechanical and electrical/electronics engineers were the most probable among engineering subfields. (See p. 66.)
- *Women scientists and engineers represented about 13 percent of the S/E workforce in 1986, up from 11 percent in 1980.* As a proportion of the total workforce, however, only about 1 percent of all employed women were working in S/E jobs in 1986, compared to almost 6 percent of all employed men. (See p. 67.)
- *Blacks continued to be underrepresented in science and engineering in 1986, accounting for only 2.2 percent of the S/E workforce.* In contrast, Asians represented almost 6 percent of those employed in science and engineering, while native American scientists and engineers represented somewhat less than 1 percent of total S/E employment. (See pp. 67-68.)
- *At the doctoral level, scientists outnumbered engineers by about five to one in 1987 (351,000 versus 68,000).* Over the 1981-87 period, total employment growth for both scientists and engineers averaged nearly 5 percent per year. (See p. 68.)
- *The job market was favorable for scientists and engineers in most S/E fields in 1986.* Unemployment rates averaged 1.9 percent for scientists and 1.2 percent for engineers, compared to 2 percent and 7.2 percent, respectively, for all professional and technical workers and the total workforce. (See p. 73.)
- *Over the 1988-2000 period, the number of jobs for scientists and engineers in private industry is expected to increase by over 600,000, with three-fifths of these new jobs to be located in the services-producing sector.* The faster creation of S/E jobs in this sector continues the trend observed between 1980 and 1988. Overall, the proportion of industry S/E jobs in the services-producing sector is expected to increase from 43 percent in 1986 to 46 percent by the year 2000. (See p. 74.)
- *Between 1988 and 2000, the occupational composition of industry jobs is expected to change away from production and assembly-line jobs toward professional, managerial, and technical occupations.* Thus, while industry as a whole is expected to provide approximately 9 percent more jobs between 1986 and 2000, employment opportunities for S/E jobs are projected to increase by about 34 percent. (See pp. 76-77.)
- *The United States led the United Kingdom in the number of scientists per 1,000 total labor force (12 versus 8 per 1,000) and was second to Japan in the number of engineers per 1,000 labor force (18 versus 19 per 1,000) in the early 1980s.* (See p. 82.)

Over the next decade, several factors will combine to substantially affect the demand for and supply of scientists and engineers. On the demand side, two factors are worthy of consideration:

(1) *The need for workers* stemming from economic growth, changing technology, and competitive challenges; and

(2) *The need to replace workers* who leave the science and engineering (S/E) workforce due to death, retirement, transfer to other occupations, and emigration.

Of the two factors, the latter will translate into the larger demand. The increases needed in new S/E workers are expected to be at lower levels of growth than in the early and mid-1980s; however, employers will need larger numbers of replacements for attrition from the overall growing S/E labor force.

On the supply side exist concerns as to the impact on future levels of new S/E graduates of a declining college-age population. This diminishing population has already resulted in a falling rate of growth in S/E bachelor's degrees. Another factor affecting the future supply of new

S/E graduates is a change in the ethnic and gender mix of the college-age population. In the future, this population will have higher proportions of minorities and women (see figure 3-1)—groups that until now have had relatively low participation rates in S/E education.[1]

These and other diverse factors will together determine the future balance of the S/E labor market. This chapter closely examines past and projected growth of S/E jobs in the industrial sector, which forms the core of demand for S/E occupations (about two-thirds of total S/E employment). Information on S/E supply is also presented. For the first time, this includes a numerical illustration and detailed analysis of S/E personnel flows into and out of the workforce.

Finally, this chapter provides comparative data on international science and engineering employment.

INDUSTRIAL S/E JOB PATTERNS

Between 1980 and 1988, the number of those employed in S/E jobs in private industry[2] increased at a rate almost twice that for all workers. (See figure O-8.) Concurrently, the occupational and industrial mix of S/E employment experienced major changes. For example, overall employment in the services-producing industries—which benefitted from substantial economic growth—increased by 29 percent. The corresponding increase in S/E employment in the sector was even greater: 57 percent. (See figure 3-2.) This increase, however, has stemmed less from growth within the sector than from an increased share of declining total manufacturing jobs.

[1]NSF (1988a), p. 29.

[2]The 1980-88 data on personnel employed in private industry S/E jobs in this section are from the U.S. Bureau of Labor Statistics Occupational Employment Statistics surveys. These surveys are of establishments and reflect employers' staffing patterns.

Science & Engineering Indicators—1989

Services-Producing Industries

The services-producing industries are divided into four major divisions:

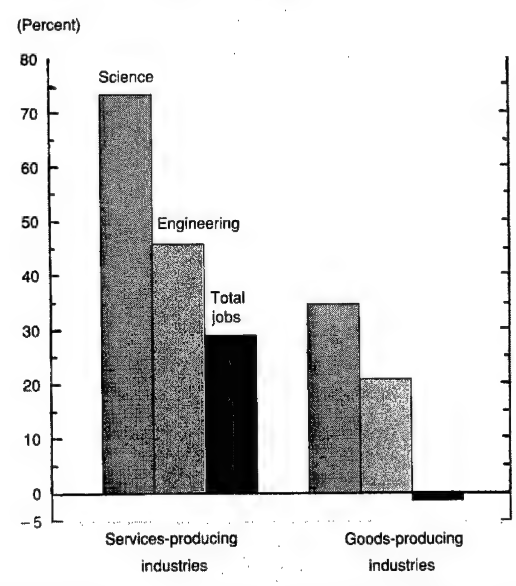
- Communications, utilities, and transportation;
- Trade;
- Financial services; and
- Business and related services.

Together, these industries provided jobs for approximately 446,000 engineers and 359,000 scientists in 1988, up from 306,000 and 207,000 (respectively) in 1980.

Over the 1980-88 period, the concentration of total S/E jobs in the private sector gradually shifted from goods-producing industries to services-producing industries. In fact, the proportion in the latter sector increased from 38 percent in 1980 to an estimated 43 percent in 1988.[3] This increase can be attributed to (1) a faster rate of employment growth for S/E personnel in services-producing industries, and (2) the sector's overall economic and employment growth. Total employment in services-producing

[3]NSF (1988b), p. 2.

Figure 3-2.
Increase in science, engineering, and total jobs in private industry, by sector: 1980-88



See appendix table 3-1. *Science & Engineering Indicators—1989*

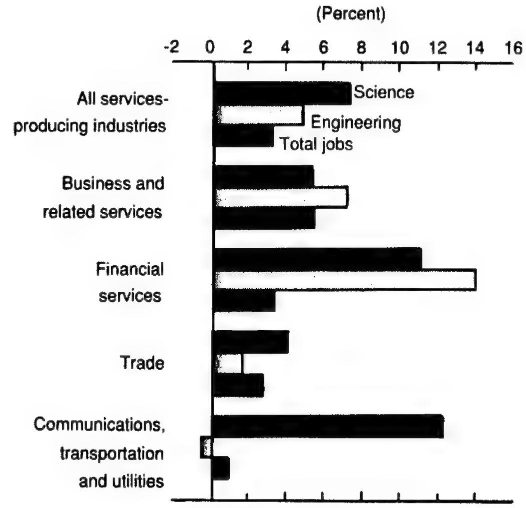
industries grew at an average annual rate of 3.2 percent between 1980 and 1988; the number of S/E jobs increased on average by 5.8 percent. The proportion of the services-producing workforce in S/E positions rose during this time from 1.3 percent of total employment in 1980 to an estimated 1.6 percent in 1988.

Business and Related Services. This was the largest and second fastest growing division of the services-producing sector over the 1980-88 period. The major employers of S/E workers in this division were involved in computer and data processing services, engineering and architectural services, and independent research and development (R&D). There were 310,000 engineering jobs and 183,000 scientist positions in this division in 1988, accounting for 70 percent and 51 percent, respectively, of the services-producing sector's engineering and science jobs in 1988. (See figure 3-3.) During the 1980-88 period, the number of jobs for engineers increased at an average rate of 7.1 percent per year, slightly higher than the 5.3-percent annual rate for scientists. (See figure 3-4.)

Several factors influenced the S/E job growth in business and related services. First, the revolution in information technologies and strong demand for information/data services created increasing employment opportunities for S/E workers in computer and data processing services. Also, new methods of delivering information-related services led to the development of major growth segments in this industry. For example, the extensive use of local area networks and electronic data interchange networks developed mostly over the past 5 years.

Financial Services. The most rapid S/E job growth in the services-producing sector occurred in the financial services division (i.e., firms engaged in banking, credit,

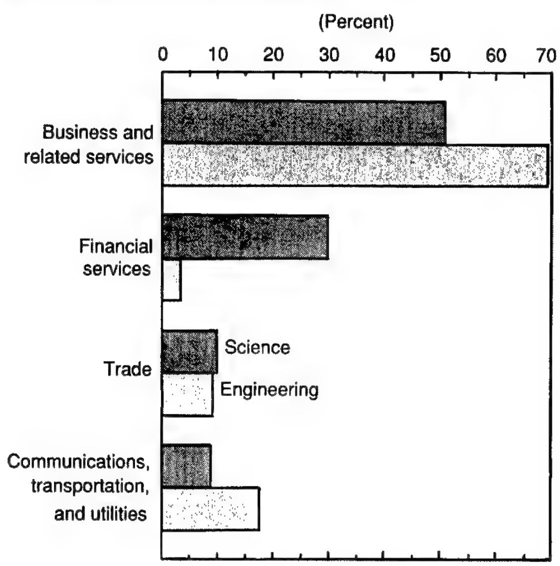
Figure 3-4.
Annual rates of growth for science, engineering, and total jobs in services-producing industries: 1980-88



See appendix table 3-1. *Science & Engineering Indicators—1989*

insurance, and real estate). Increasing use of technological advances and computerized services resulted in greater requirements for computer specialists and mathematical and social scientists. Between 1980 and 1988, jobs for these workers rose at an average annual rate of 11 percent; further, workers in these fields accounted for approximately 90 percent of this division's 122,000 S/E jobs in 1988.

Figure 3-3.
Distribution of science and engineering jobs in services-producing industries: 1988



See appendix table 3-1. *Science & Engineering Indicators—1989*

Factors Behind Growth in Service Industries. The recent growth of service industries and their S/E employment is not simply due to a transfer of jobs to them by goods-producing industries as these latter contract out activities formerly performed in-house. Such transference is not a major factor, since both the numbers and share of total employment in technical occupations within the goods-producing sector are increasing. Also, according to a recent study by the U.S. Bureau of Labor Statistics (BLS), the transfer of work formerly done in-house by manufacturers accounted for—at best—only a small fraction of the growth in the services-producing sector.

Rather, the growth in industries serving producers has been primarily attributed to increases in the supply of new services.[4] The continued development of new services should keep demand growing for the outputs of these industries even as scientific and technical employment in the goods-producing industries that they service continues its upward growth.

Goods-Producing Industries

The goods-producing industries fall into the major divisions of:

[4]Tschetter (1987).

- Durable goods manufacturing,
- Nondurable goods manufacturing,
- Mining, and
- Construction.

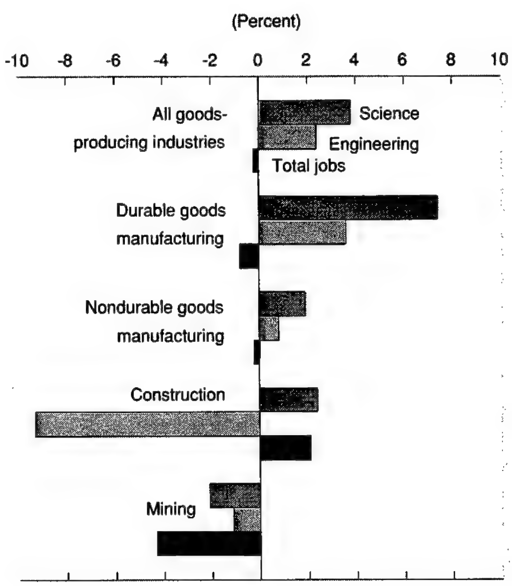
Together, these divisions provided jobs for 830,000 engineers and 225,000 scientists in 1988, compared to 686,000 and 167,000—respectively—in 1980.

S/E jobs in goods-producing industries expanded at an average rate of 2.7 percent per year between 1980 and 1988. (See figure 3-5.) Unlike the services-producing industries, total employment in this sector experienced no growth over this period: a small increase in total employment growth in construction was offset by declines in the mining and both manufacturing divisions. S/E job growth in the manufacturing divisions was maintained for several reasons, including increases in:

- Defense spending,
- Technological competition,
- Pressure to improve productivity,
- High-technology capital investment, and
- R&D expenditures.

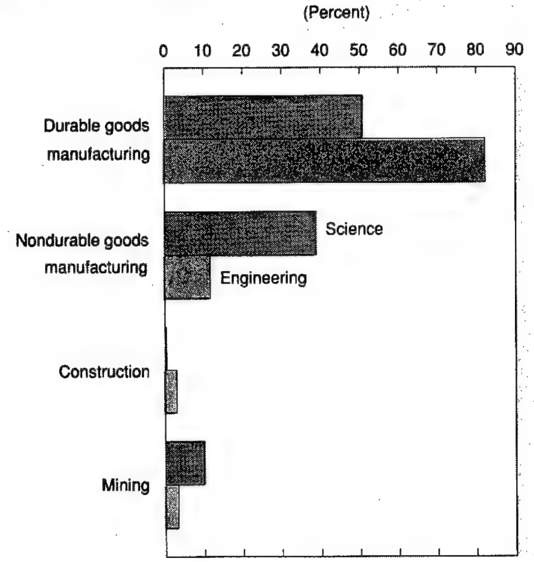
Durable goods manufacturing was the largest provider of S/E jobs in the goods-producing sector; in 1988, over 80 percent of the sector's engineering jobs, and 51 percent of its science jobs, were in this division. (See figure 3-6.) Major S/E employers within this division in 1988 were:

Figure 3-5.
Annual rates of growth for science, engineering, and total jobs in goods-producing industries: 1980-88



See appendix table 3-1. *Science & Engineering Indicators—1989*

Figure 3-6.
Distribution of science and engineering jobs in goods-producing industries: 1988



See appendix table 3-1. *Science & Engineering Indicators—1989*

- Aerospace industries (manufacturers of aircraft and parts, space vehicles, and guided missiles) with 24 percent of the division's S/E jobs;
- Makers of communication equipment, 15 percent;
- Office and computing equipment manufacturers, 12 percent; and
- Electronic components industries, 12 percent.

Occupations

While industry as a whole was providing increasingly greater employment opportunities in almost all S/E occupational categories between 1980 and 1988, services-producing industries remained the primary source of employment for most scientists (most notably computer specialists and social scientists), while engineers continued to find more job opportunities in the goods-producing sector. The proportion of scientists employed in services-producing industries rose in every major category between 1980 and 1988. The share of most engineering subfields in the goods-producing sector increased a small amount over the period. The goods-producing and services-producing sectors showed similar occupational patterns of S/E employment in 1988.

UTILIZATION OF S/E PERSONNEL

Employment Levels and Demographic Trends

In 1988, approximately 5.9 million persons in the United States were—by virtue of their education and work experience—considered scientists (2.8 million) or engineers

(3.1 million).[5] Only 72 percent of these scientists (2.0 million) and 85 percent of these engineers (2.6 million) were in the S/E workforce, however. The remaining scientists and engineers were either employed in non-S/E jobs, unemployed and seeking employment, or outside the labor force.

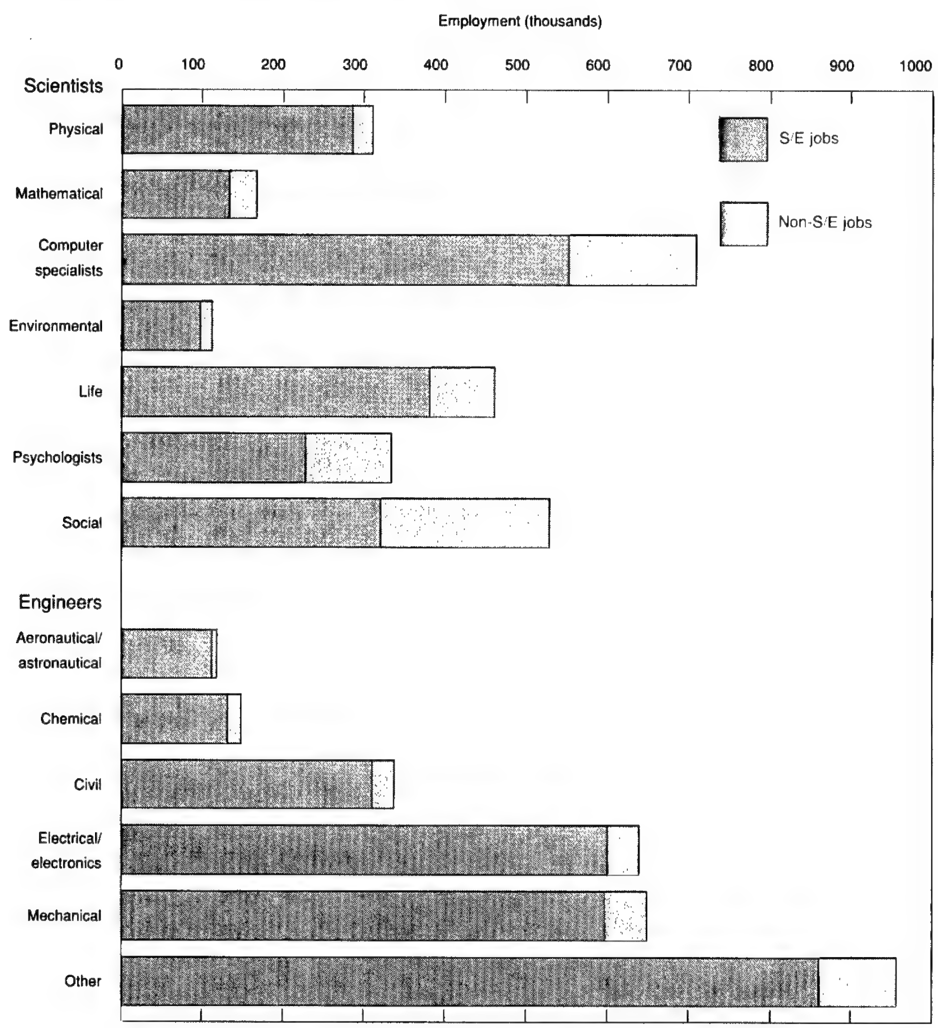
Scientists and engineers employed in non-S/E jobs are not necessarily underutilized, however, since their S/E training and education may be prerequisites for—or provide valuable inputs to—their work. Of those scientists who reported non-S/E employment in 1988, almost one-third (208,000) were social scientists, and approximately one-fourth (158,000) were computer specialists. (See figure 3-7.) Among engineers employed in non-S/E activities at that time, one-fifth (51,000) were mechanical engineers and another 17 percent were electrical/electronics engineers.

Overall S/E Employment Growth and Concentration.[6] Employment growth of scientists in the S/E workforce varied from that of engineers during the 1980-88 period. Science employment nearly doubled during this time; employment of engineers increased by almost 75 percent. (See

[5]Broadly speaking, a person is considered a scientist or engineer if he or she meets at least two of the following criteria:
- Has earned a degree in science (including social science) or engineering,
- Has been employed in an S/E occupation, and/or
- Has professionally identified himself or herself as a scientist or engineer on the basis of total education and work experience.

[6]S/E employment includes only those scientists and engineers employed in science and engineering jobs, unless otherwise indicated. Technician and other occupational groups that may be engaged in S/E-type work are not included.

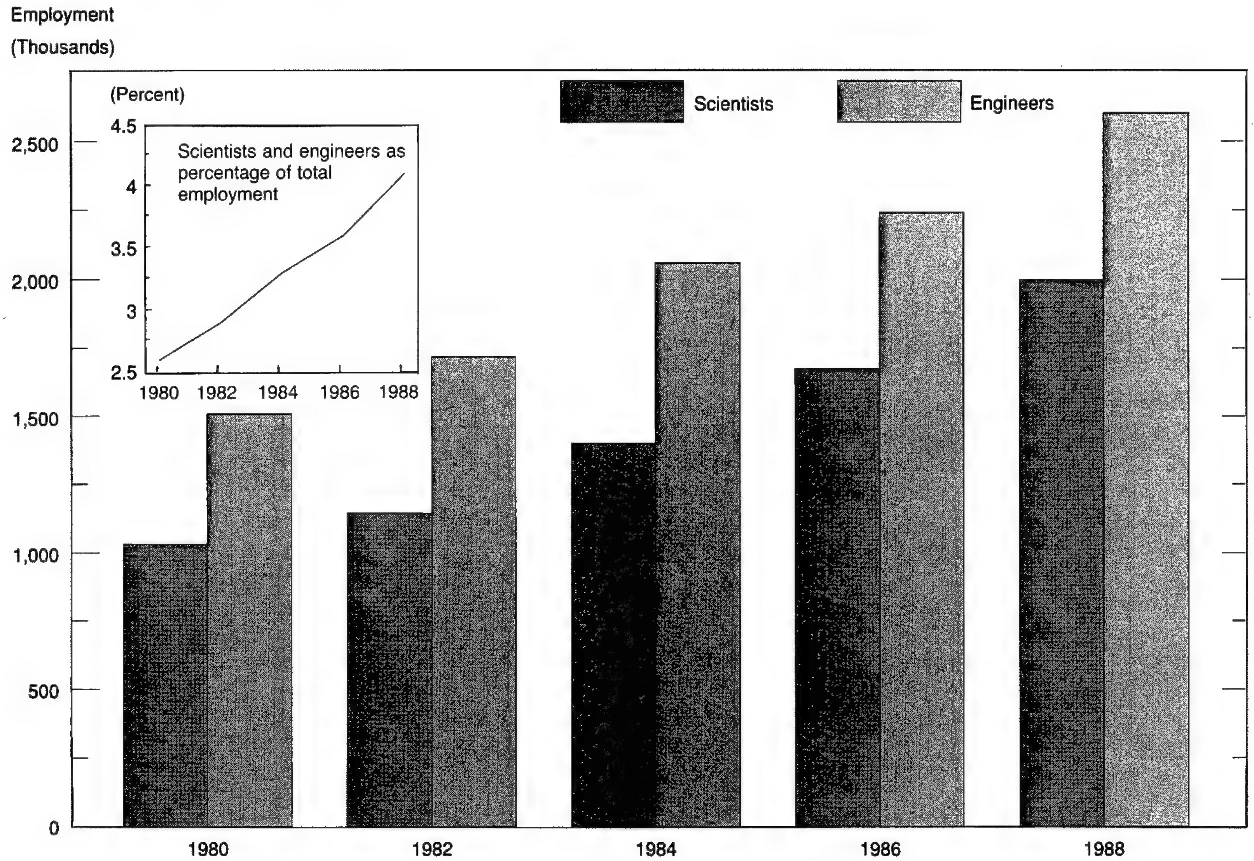
Figure 3-7.
Employment status of scientists and engineers, by field: 1988



See appendix tables 3-2 and 3-3.

Science & Engineering Indicators—1989

Figure 3-8.
Scientists and engineers employed in S/E jobs: 1980-88



See appendix tables 3-2 and 3-8. *Science & Engineering Indicators—1989*

figure O-9 in Overview.) Overall, the S/E workforce grew by 7.8 percent per year during this period. In comparison, total U.S. employment increased by only 1.8 percent per year.[7] Consequently, the proportion of the workforce employed in science and engineering grew from 2.6 percent in 1980 to 4.1 percent in 1988. (See figure 3-8.) In addition, real gross national product (GNP)—an indicator of overall economic activity—increased at an annual rate of only 3.0 percent over the period.[8]

Almost half of both scientists and engineers in the S/E workforce were concentrated in either of two fields in 1988. Among scientists, 47 percent were employed as either computer specialists or life scientists; for engineers, 46 percent were either electrical/electronics or mechanical engineers.

Employment of Women and Minorities. Approximately 13 percent of the S/E workforce were women in 1986, up from 11 percent in 1980. As a proportion of the total workforce, however, only about 1 percent of all employed women were working in S/E jobs in 1986, compared to almost 6 percent of all employed men.[9] Women accounted for a much larger share of employment in the science workforce than in engineering. While almost 26 percent of scientists in the S/E workforce were women in 1986, only 4 percent of engineers were female. (See figure O-10 in Overview.) Among scientists, women represented 42 percent of all psychologists in 1986, but only about 13 percent of the physical and environmental scientists. In engineering, women accounted for between 3 percent of both mechanical and electrical/electronics engineers and almost 8 percent of chemical engineers.

Blacks accounted for only 2.2 percent of those employed in S/E jobs in 1986. (See figure 3-9.) In the general workforce, they represented 10 percent of total U.S. employment and almost 7 percent of those employed in the professional and related workforce.[10] In contrast, Asians represented less than 2 percent of the U.S. labor force and only 3 percent of those in professional fields,[11] but almost

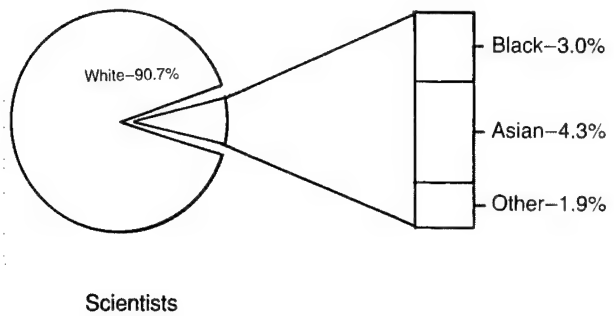
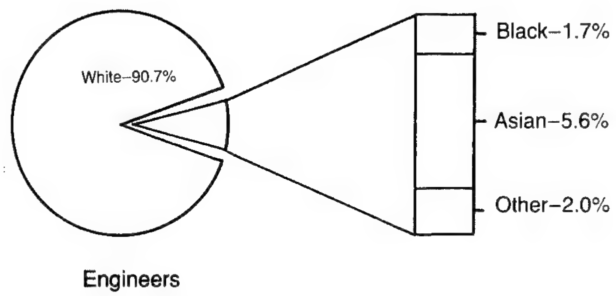
[10]U.S. BLS (1987a), p. 179.
[11]U.S. Bureau of the Census (1983).

Figure 3-9.
Distribution of scientists and engineers employed in S/E jobs, by race: 1986





See appendix table 3-4. *Science & Engineering Indicators—1989*

6 percent of all scientists and engineers. Native American scientists and engineers represented somewhat less than 1 percent of total S/E employment; this was roughly similar to their participation in the overall U.S. labor force.[12, 13]

Approximately 2.1 percent of the scientists and engineers in the S/E workforce in 1986 were Hispanic.[14] Roughly 6.6 percent of all employed persons were of Hispanic origin, as were 3.3 percent of those in professional and related occupations.[15]

Doctoral Scientists and Engineers

Employment of those holding science and engineering doctorates reached 419,000 in 1987, an increase of 22 percent since 1981.[16] The employment growth of S/E doctorate-holders between 1981 and 1987 slowed from that of prior years, increasing by 3.3 percent per year versus 4.8 percent per year between 1977 and 1981.

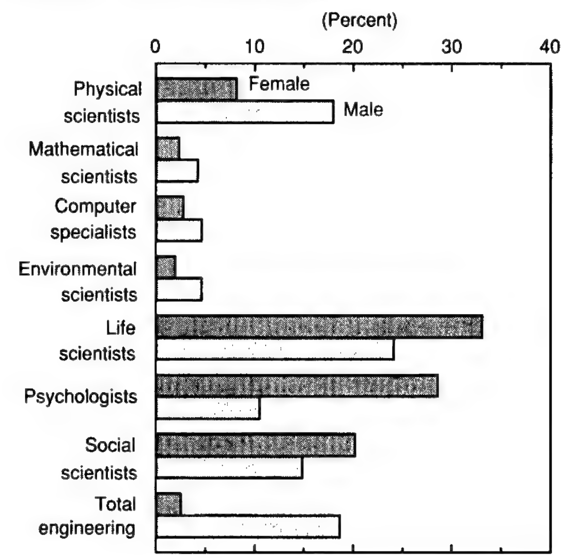
Because scientists are more highly concentrated than engineers in academia, where higher levels of education are required for professional status, there is a higher proportion of science doctorate-holders. In fact, scientists at the doctoral level outnumbered engineers by about five to one in 1987 (351,000 versus 68,000); this ratio was virtually unchanged during the 1980s.

In 1987, doctoral women and men scientists and engineers were employed in different fields. A higher proportion of Ph.D. women (97 percent) than men (81 percent) were scientists; over four-fifths of these women were in either the life sciences, psychology, or the social sciences. (See figure 3-10.) Ph.D. men, in contrast, were concentrated in either the life or physical sciences. Within engineering, women doctorate-holders were more likely to be concentrated in either electrical/electronics or materials engineering; men were most likely to be employed in electrical/electronics engineering.

Blacks constituted only about 1.5 percent (6,400) of all employed doctoral scientists and engineers in 1987: this was a slight (1.3 percent) increase over 1981. The almost 37,000 employed Asians in 1987 represented about 9 percent of the total, up slightly from 8 percent in 1981. (See figure 3-11.)

Hispanic Ph.D. scientists and engineers represented 1.6 percent of all doctoral scientists and engineers in 1987, up from 1.4 percent in 1981. Among doctorate-holders, Hispanics were slightly more likely than all Ph.D.s to be scientists rather than engineers.

Figure 3-10.
Distribution of employed doctoral scientists and engineers, by field and gender: 1987



See appendix table 3-5. *Science & Engineering Indicators—1989*

---

[12]Ibid.

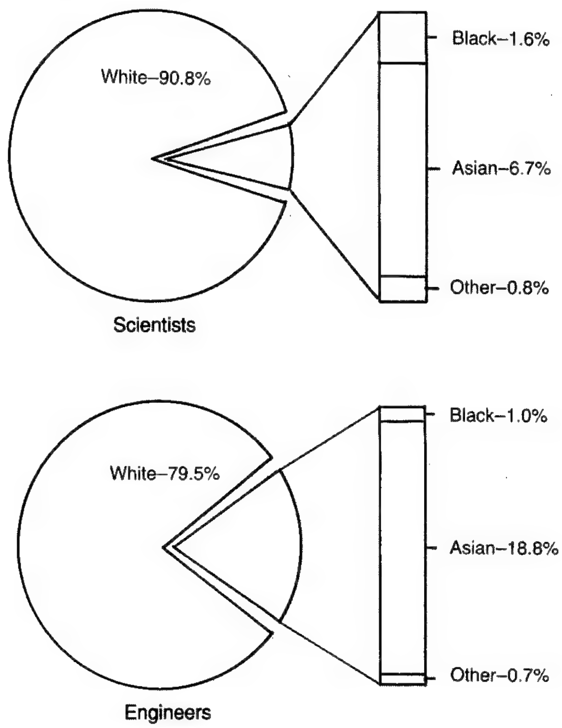
[13]Data for native Americans should be viewed with caution, however, since the estimates for both scientists and engineers and for the overall U.S. labor force are based on an individual's own classification as to his or her native American heritage; such perceptions may change over time.

[14]Hispanics are a diverse ethnic group, and it would be desirable to distinguish among Mexican Americans, Puerto Ricans, and other Hispanics, since their respective socioeconomic backgrounds and reasons for underrepresentation may differ. Because of data limitations, however, the present discussion on Hispanics treats them in aggregate.

[15]U.S. BLS (1987a), p. 179.

[16]This 419,000 includes 40,500 S/E doctorate-holders employed in non-S/E jobs. Detailed data comparable to that for all scientists and engineers employed in S/E jobs are not available.

Figure 3-11.
Distribution of employed doctoral scientists and engineers, by race: 1987



See appendix table 3-6. *Science & Engineering Indicators—1989*

SUPPLY AND DEMAND FOR S/E PERSONNEL—LABOR MARKET INDICATORS

The demographic employment trends discussed above indicate that women and ethnic minorities have been steadily increasing their representation within a rapidly growing science and engineering workforce. These trends, however, do not indicate whether the S/E workforce has expanded sufficiently to keep pace with the needs of the economy. To help assess S/E labor market balance, and the extent to which the S/E workforce is utilizing women and minorities, several labor market indicators can be used. General measures of S/E supply and demand conditions include:

- Labor force participation rates,
- Unemployment rates,
- S/E employment rates,
- Experience of recent S/E graduates,
- Recent hiring experiences of S/E employers, and
- Trends in S/E recruitment.

While no single statistic can provide a firm basis for measuring shortages or surpluses of scientists and engineers, some statistics—when analyzed together—allow for meaningful inferences about the condition of the S/E labor market.

Labor Force Participation Rates

The S/E labor force includes scientists and engineers who are employed—either in or out of science and engineering—and those who are unemployed but seeking employment. The labor force is a measure of those who are economically active and thus directly available to carry out national efforts in science and technology. Labor force participation rates measure the fraction of the S/E population in the labor force. Low rates would suggest that many of those with S/E training and skills are not using these skills in S/E or other jobs.

In 1986, approximately 95 percent of the S/E population was in the labor force, with scientists and engineers equally likely to be working or seeking employment. This rate is higher than the 82-percent rate for the general population with 4 or more years of college.[17]

The difference in participation rates cannot be accounted for by differences in the gender composition of the S/E versus the general population. Stratification by gender shows that the participation rate for women in science and engineering was about equal to that for men (94 percent versus 95 percent), with little variation among S/E fields. In comparison, women and men in the general population who had completed 4 or more years of college had participation rates of 74 percent and 88 percent, respectively. Over the 1980-86 period, participation rates increased for women scientists and engineers, rising from 90 percent in 1980; rates remained stable for men.

Black scientists and engineers reported a labor force participation rate of 97 percent in 1986. This was slightly higher than the 96-percent rates for both Asians and native Americans; for whites, the rate was 94 percent. The S/E participation rate for blacks was much higher than that for blacks in the overall population (63 percent) or for black college graduates (87 percent). Since 1980, the labor force participation rate for black scientists and engineers has remained relatively stable; for Asians, the rate has declined from 98 percent in 1980.

Unemployment Rates

A standard measure of labor market conditions is the unemployment rate, which measures the proportion of those in the workforce who are not employed but seeking work. In the 1980s, scientists and engineers have been maintaining their labor market position, although they have been outperformed by both the general labor force and all professional and related workers. In 1980, the unemployment rates for scientists and engineers were 1.6

[17] U.S. BLS (1987c).

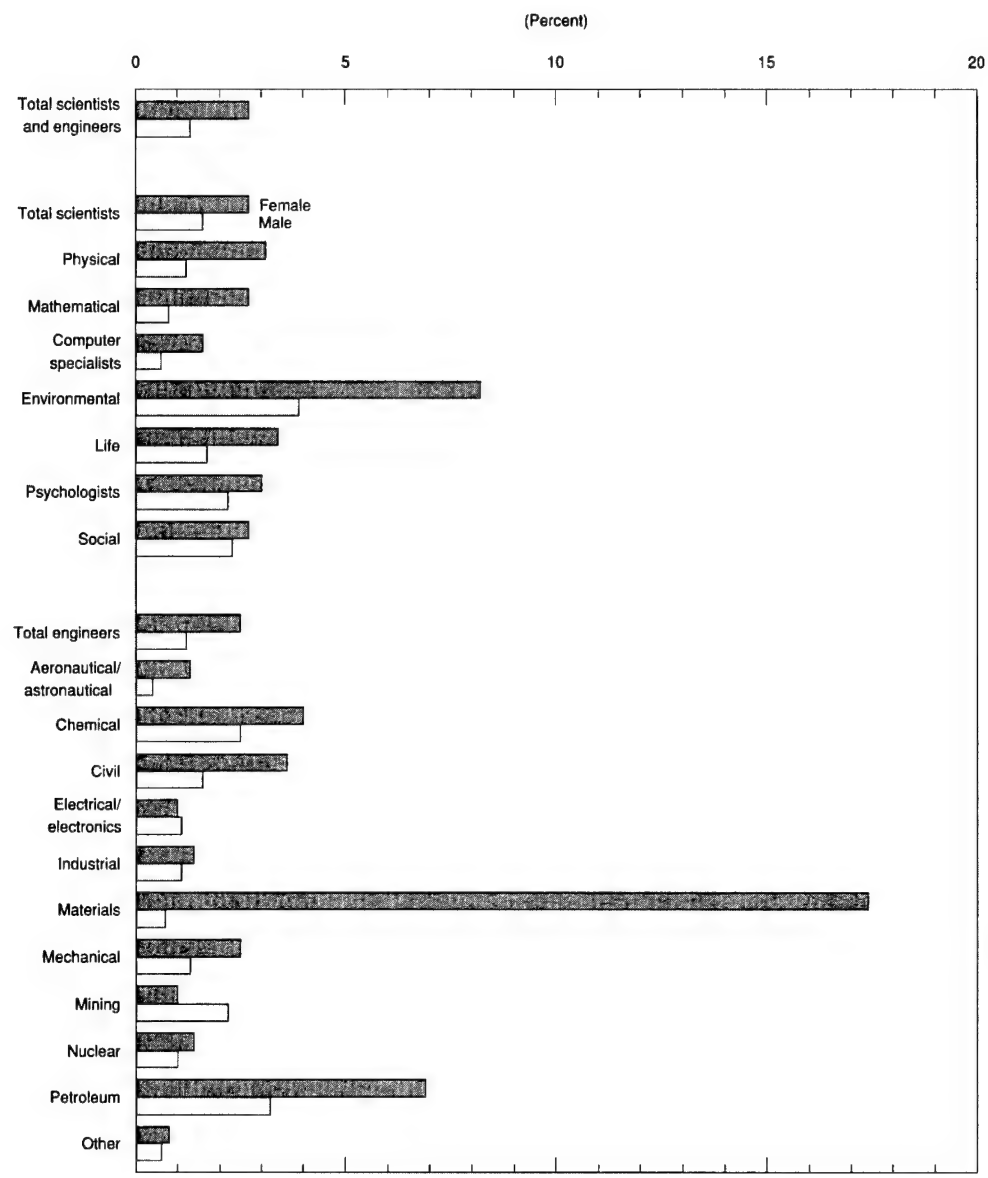
percent and 1.0 percent, respectively, compared to 2.5 percent for all professional and technical workers and 7.1 percent for the entire U.S. workforce. In 1986, the rate for all professional and technical workers had fallen to 2.0 percent and the rate for the total workforce rose to 7.2 percent.[18] S/E unemployment increased slightly faster, rising to 1.9 percent for scientists and 1.2 percent for engineers in 1986.

Comparisons by gender show that the unemployment rate for women scientists and engineers was more than twice that for men in 1986: 2.7 percent versus 1.3 percent. (See figure 3-12.) The rate for S/E women was substantially lower than that for all women in the United States (7.1 percent), but similar to that for women in professional occupations (2.3 percent) and women college graduates (2.4 percent). Since 1980, unemployment rates for both women and men scientists and engineers have increased from 1.5 percent and 1.0 percent, respectively.

The unemployment rate for black scientists and engineers in 1986 averaged 3.8 percent; this rate was more than twice that for white scientists and engineers (1.5 percent) and Asians (1.8 percent), and more than three

[18] U.S. BLS (1987a), p. 168.

Figure 3-12.
Unemployment rates of scientists and engineers, by field and gender: 1986



See appendix table 3-7.

Science & Engineering Indicators—1989

times higher than the rate for native Americans (1.2 percent).

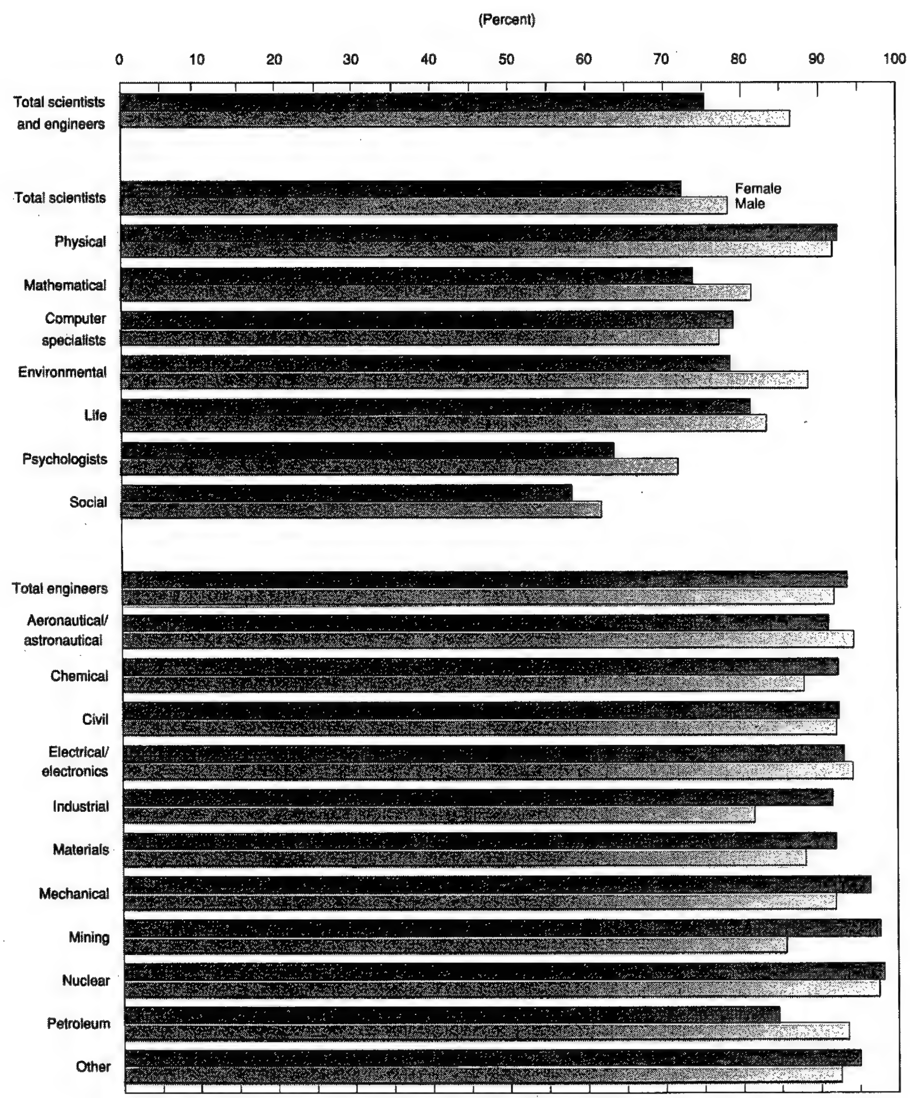
S/E Employment Rates

The S/E employment rate measures the extent to which employed scientists or engineers have an S/E job. Reasons for non-S/E employment include lack of available S/E jobs, higher pay for non-S/E employment, location, or preference for a job outside of science and engineering.

In 1986, the S/E employment rate was 85 percent (down from 89 percent in 1980); the rate for engineers (92 percent) was substantially above that for scientists (77 percent). (See figure 3-13.) Within science fields, the rates ranged from 61 percent in the social sciences and 78 percent in the computer specialties to 87 percent in the environmental and physical sciences.

Rates by Gender. Women scientists and engineers are less likely than men to work in science- or engineering-related activities. In 1986, the S/E employment rate for women was 75 percent; that for men was 80 percent. These rates have declined steadily for both women and men throughout the eighties: in 1980, the rates were 87 percent and 89 percent, respectively. The somewhat larger decline for women partially reflects their high concentrations in psychology and social science—fields in which S/E employ-

Figure 3-13.
Science and engineering employment rates, by field and gender: 1986



See appendix table 3-7.

Science & Engineering Indicators—1989

ment rates have fallen dramatically during the eighties for both women and men. More than one-third of women, compared with about one-tenth of men, were in one of these fields in 1986.

S/E employment rates for men and women vary by field, with the widest fluctuations occurring in the sciences. In 1986, the S/E employment rate for women scientists was 72 percent, compared with 78 percent for men. In engineering, however, the rate for women (94 percent) was above that for men.

Rates by Race. The S/E employment rate for black scientists and engineers was 77 percent in 1986, compared to 85 percent for whites and 88 percent for Asians. The higher rate for Asians in 1986 reflects the relatively large proportion of Asians who are engineers rather than scientists. On average, the S/E employment rate for Asian engineers was 95 percent in 1986, compared to 92 percent for whites and 90 percent for blacks. The S/E employment rate for black scientists was below that for whites and Asians across most major fields of science except mathematics: here the rate for blacks (90 percent) was above that for both whites (79 percent) and Asians (70 percent).

Experience of Recent S/E Graduates

The experience of recent S/E graduates is another indicator of the degree of market balance. In general, if the demand for scientists and engineers is greater than the supply at existing salary levels, the proportions of recent graduates who obtain jobs in science or engineering will be relatively high. Those proportions, however, vary considerably by field. This section presents data from a 1986 national survey of 1984 and 1985 bachelor's and master's degree recipients.

Unemployment Rates. In 1986, relatively few recent S/E graduates were unable to find employment; only 3.7 percent of the graduates with bachelor's degrees in science, and 2.4 percent of those with engineering degrees, reported that they were unemployed. For master's degree recipients, the rates were 2.6 percent for those with degrees in science and 1.2 percent for recipients of engineering degrees.

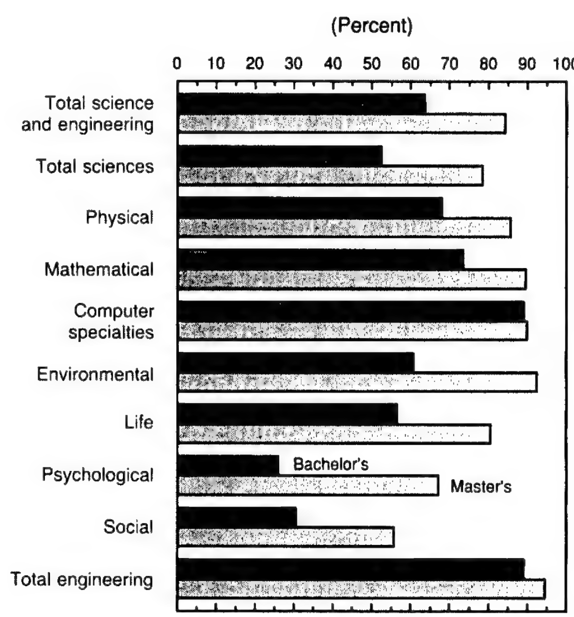
Unemployment rates were similar for men and women at the baccalaureate level; some differences began to arise at the master's degree level, however. For those who received their degrees in 1984 or 1985, unemployment rates for recent S/E bachelor's recipients were 3.4 percent (men) and 3.7 percent (women) in 1986. At this level, unemployment rates for women were below those for men in mathematics, the environmental sciences, psychology, and almost all engineering subfields. At the S/E master's degree level, the rate for women (3.2 percent) was almost twice that for men (1.7 percent). With little exception, women's unemployment rates were higher than men's across all fields.

S/E Employment Rates. S/E employment rates for recent S/E graduates with master's degrees were similar to those for more experienced scientists and engineers, while the rates for bachelor's degree recipients were lower.[19] The greater opportunities for employment in science and, to a lesser extent, engineering jobs for master's degree-holders may reflect the higher levels of investment in field-specific training; fewer S/E job openings at the bachelor's level may indicate entry-level job requirements for advanced degrees.

For both master's and bachelor's degree recipients, S/E employment rates varied between scientists and engineers. (See figure 3-14.) At the master's level, 79 percent of science graduates were working in S/E occupations, compared with 95 percent of engineering graduates. For most science fields, almost 90 percent of those with master's degrees were employed in S/E occupations; the life (81 percent) and social sciences (56 percent) were the exceptions. Although rates were lower for bachelor's degree recipients, the same general pattern prevailed. The average rate for engineers (89 percent) was substantially higher than that for scientists (53 percent); the lowest rate was recorded by social scientists (31 percent).

The S/E employment rates for men generally were higher than those for women at both the bachelor's and master's degree levels. The specific field concentrations of each gender contributed to some of the difference in these rates. For example, the low S/E employment rate in the social and behavioral sciences, coupled with the concentration of women in these fields, effectively lowered the average S/E employment rate for women. On the other hand, the high S/E employment rate in engineering—in which men were predominant—had the effect of raising men's average rate.

Figure 3-14.
Percentage of recent science and engineering degree recipients employed in S/E jobs: 1986



See appendix table 3-10. *Science & Engineering Indicators—1989*

[19] NSF (1987), p. 89.

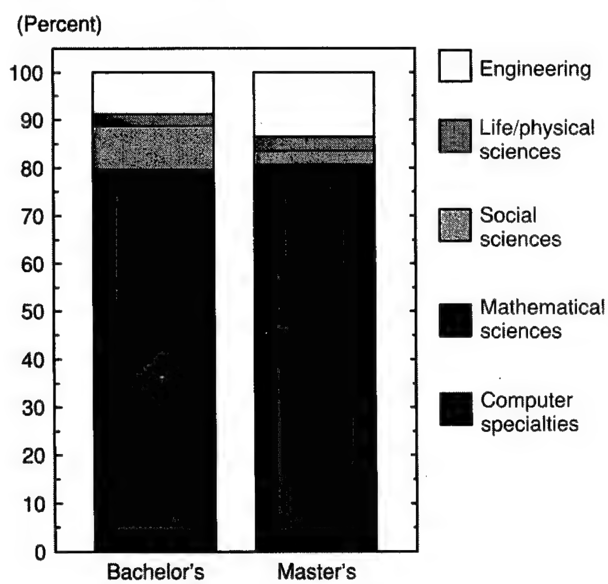
Mobility. Substantial field mobility can be identified at entry to the labor market, a characteristic resulting from supply/demand adjustments and flexibility of S/E personnel. In 1986, for example, 30 percent of the recent bachelor's and 23 percent of recent master's graduates working as computer specialists did not receive their degrees in the computer sciences. (See figure 3-15.) Rather, graduates in mathematics, engineering, and the social sciences—responding to the job opportunities in computer specialties—accounted for the majority of influx from other S/E fields.

Employer Shortages of S/E Personnel

Another direct indicator of S/E supply and demand imbalances in the S/E labor market is the reported experience of employers in meeting their staffing requirements. An NSF survey of the industrial S/E labor market, conducted in January 1989, found that nearly 46 percent of the establishments in major S/E-employing industries report a shortage in at least one field of science or engineering. While many establishments reported shortages, such positions were distributed across a variety of S/E fields and were not concentrated in a single discipline.

Science and engineering fields with the highest reported levels of shortages were:

Figure 3-15.
Degree field of 1984 and 1985 S/E graduates working as computer specialists in 1986



See appendix table 3-9. *Science & Engineering Indicators—1989*

- Electronics engineering—22 percent of employers reporting;
- Chemistry—21 percent;
- Electrical engineering, computer engineering, and computer science—20 percent each; and
- Chemical engineering—18 percent.

Across all fields, 80 percent of the employers of scientists, and 75 percent of the employers of engineers, reported plans to hire experienced personnel rather than new college graduates, indicating that the supply of new graduates is less of a problem.

The equilibrium between S/E supply and demand improved since the beginning of the 1980s, when at least one-half of the employers of most engineering and computer specialties subfields reported shortages.[20]

Engineering schools in the U.S. have reported what may be considered serious and persistent shortages of faculty. In 1986, almost 9 percent of authorized full-time engineering faculty positions were unfilled. Furthermore, many institutions reported that the authorized levels would be higher if it were possible to fill such positions.[21] Shortages of engineering faculty are grounded in the long-term decline in engineering doctorates awarded to U.S. citizens,[22] and the increasing demand for engineering Ph.D.-holders in the industrial sector.

High Technology Recruitment Index

The Deutsch, Shea, and Evans High Technology Recruitment Index (HTRI) is another indicator of S/E labor market conditions. The HTRI measures the amount of advertising space in national newspapers devoted to recruiting scientists and engineers. Starting in 1975, the index measured 69. By 1979, the index had risen to 145, reflecting the surge in S/E recruitment that occurred toward the end of that decade. Following the recession in the early eighties, the HTRI dropped to 102 in 1983, before recovering strongly to 134 in 1984.

In the last 5 years, the HTRI has gradually declined, registering 103 in the second quarter of 1989—the lowest level of activity since 1983. (See figure 3-16 and appendix table 3-11.)

Summary

The employment indicators discussed above suggest that the labor market situation for scientists and engineers has been favorable since the mid-1980s. For example, it can be inferred from the relatively high participation rates and low unemployment rates that, in 1986, there was generally sufficient demand to accommodate the S/E labor force

(including recent S/E graduates). In addition, the moderate levels of shortages reported by employers in 1988 and the declining S/E HTRI would indicate that—with the exception of engineering Ph.D.s—the S/E labor force has, in general, been nearly sufficient to meet the economy's current needs. Finally, the data indicate that women and blacks are generally better utilized (relative to men and whites) in engineering than in the sciences.

On the other hand, however, the balance between supply and demand for S/E personnel has been accomplished through means other than new S/E graduates with fully appropriate training in their occupational field. Substantial occupational mobility[23] and increasing reliance on foreign-origin personnel (native-born U.S. citizens declined from 90 percent of the S/E labor force in 1972 to 83 percent in 1982)[24] have been largely responsible for the supply/demand equilibrium in the science and engineering labor market.

PROJECTED S/E DEMAND IN INDUSTRY

Over the 1988-2000 period, U.S. private industry is expected to create more than 600,000 additional jobs for scientists and engineers.[25] S/E employment is projected to increase by over 33 percent, nearly four times that of the overall industrial labor force. (See figure 3-17.) Despite the substantial growth, the projected gains in S/E requirements should not match past increases, due to the overall slowdown expected in the 1990s of growth in the labor force, total employment, and GNP.

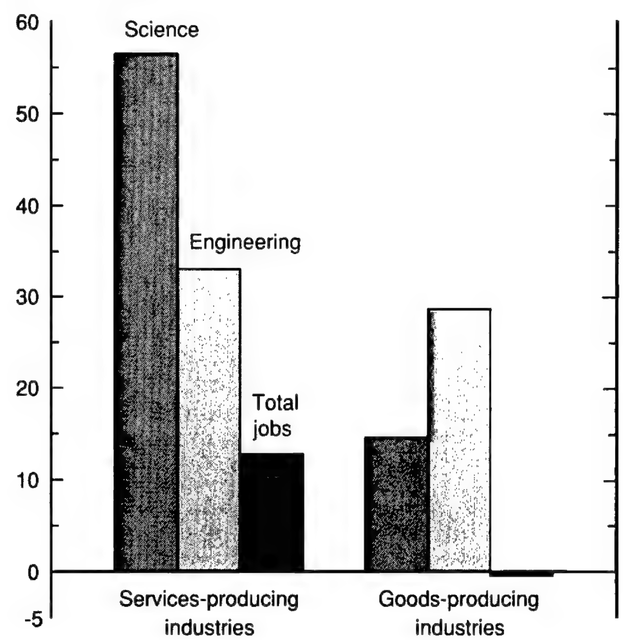
Services-Producing Industries

The 2.5 million S/E jobs in the year 2000 are expected to be somewhat more concentrated in services-producing industries than were the 1.9 million S/E jobs in 1988, because almost three-fifths of the increase in S/E jobs is projected to be in this sector. The faster creation of S/E jobs in the services-producing sector should continue the trend observed since 1980. At the projected rates of growth, the proportion of science jobs in the services-producing industries would increase from 62 percent in 1988 to almost 68 percent by 2000; the percentage of engineering jobs would go from 35 percent to 36 percent during this period. (See figure 3-18.)

Total job growth is expected to be very strong for almost all of the services-producing industries through the year 2000. By that time, services-producing employment should constitute about 70 percent of all private industry jobs. Almost 7 million new jobs are projected to be added to the sector between 1988 and 2000.

Figure 3-17.
Projected increase in science, engineering, and total jobs in private industry: 1988-2000

(Percent)



See appendix table 3-1. *Science & Engineering Indicators—1989*

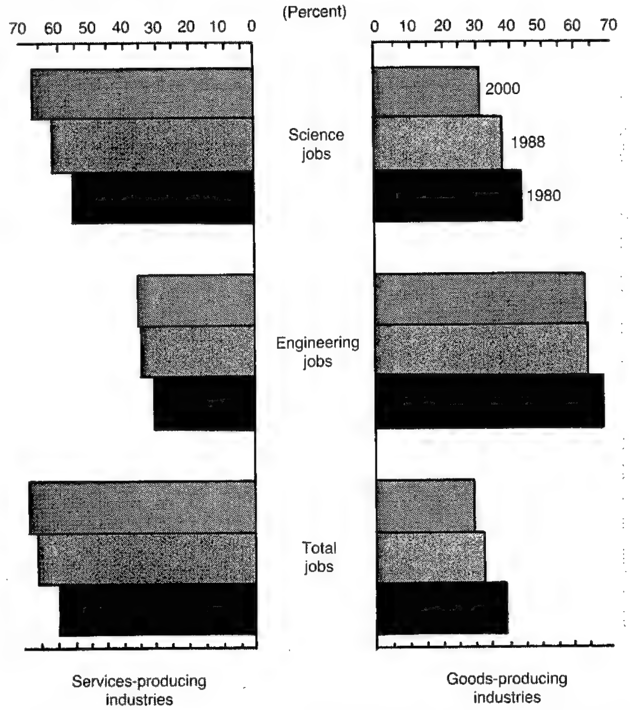
[23]Dauffenbach and Finn (1984).

[24]NSF (1986), p. 39.

[25]The projections of private industry's requirements for scientists and engineers used here were generated by NSF utilizing a modeling system developed by Data Resources (DRI), a private firm specializing in economic forecasting. NSF specified three projection scenarios—a "low," a "high," and a "mid"—using alternative sets of economic assumptions designed to encompass likely private sector performance during the simulation period of 1988-2000. (See appendix table 3-1a.) Based on these assumptions, the DRI model generated estimates of projected total employment by industry. The occupational structure applied to the total employment projections was developed by BLS.

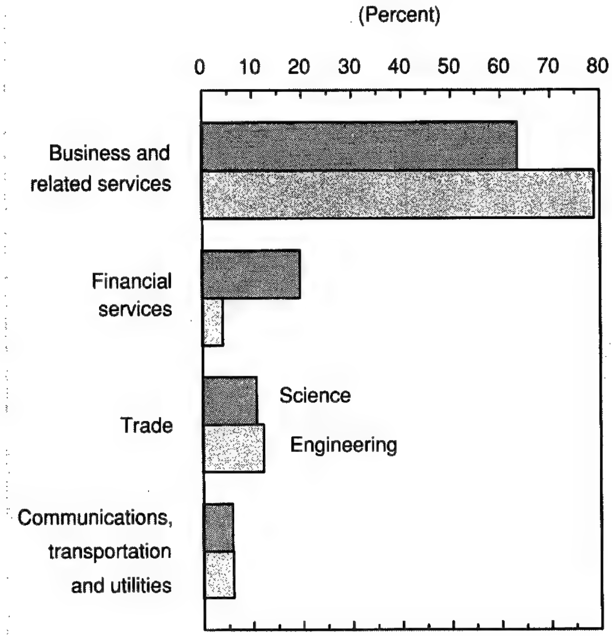
The scenarios are *not* predictions; consequently, departures from the assumptions on which the scenarios are based may alter future outcomes significantly. Three estimates of future requirements were prepared—a low, a high, and a mid trend; analysis here focuses on the mid trend.

Figure 3-18.
Proportion of science, engineering, and total jobs in private industry, by sector: 1980, 1988 and projected 2000



See appendix table 3-1. *Science & Engineering Indicators—1989*

Figure 3-19.
Distribution of new S/E jobs to be created in services-producing industries: 1988-2000



See appendix table 3-1. *Science & Engineering Indicators—1989*

Jobs for scientists and engineers are expected to grow even faster than total sector employment due to an increasing share of that employment. Overall, employment in services-producing industries is projected to be about 13 percent higher in 2000 than in 1988; S/E employment is expected to increase by almost 44 percent. The proportion of the services-producing workforce in S/E jobs is projected to increase during this time from 1.6 percent in 1988 to 2.0 percent by 2000, providing jobs for approximately 550,000 scientists and 600,000 engineers.

Business and Related Services. This division will be the sector's major provider of new S/E jobs through the year 2000. About two-thirds of the new science positions and three-fourths of the new engineering jobs expected to be created in the services-producing sector will be generated in this division. (See figure 3-19.) The number of S/E positions in business and related services industries is expected to rise by almost 65 percent to about 740,000—this represents 64 percent of the sector's S/E jobs in 2000.

Growth in this division will derive from the need for systems design and analysis and software development. This need is expected to continue to be very strong, reflecting the increasing demand for specialized systems by business and government, as well as the proliferation of packaged software for a wide variety of users. BLS projects that heavy investment in computer-assisted design and manufacturing techniques will lead to a continuing increase in the demand for computer specialists.[26] In addition, the development of new services should keep demand for independent research laboratories and management and other consulting firms very strong.

The engineering and architectural services industry—the largest employer of engineers in the private sector—is expected to turn around from current declines brought on by low demand in recent years for its services by a principal customer, the nonresidential construction industry. The latter is projected to recover from the recent oversupply of office and commercial space, and will resume modest growth. Consequently, S/E job opportunities in engineering and architectural services will increase.

Financial Services. S/E jobs in this division should continue to grow faster than in most other industries. As the growth in demand for financial services proceeds unabated, S/E jobs are expected to increase from 122,000 in 1988 to almost 168,000 in the year 2000, reflecting greatly increasing use of computerized services and technological advances.

[26]For an analysis of long-range economic trends and their projected impact on employment, see Personick (1987).

Goods-Producing Industries

The goods-producing industries are projected to provide almost 1.1 million jobs for engineers and 270,000 jobs for scientists by 2000. Like the trend observed between 1980 and 1988, there will be little if any growth in total employment in the goods-producing sector: declines in mining and nondurable goods manufacturing will offset small growth in construction and durable goods manufacturing. Output growth in most manufacturing industries is expected to continue at near current rates without a coincident growth—and even (for some industries) with declines in—total employment. The forces behind this output growth are:

- Investment, leading to higher productivity of the manufacturing workforce; and
- The growing quality of the services purchased from the services-producing sector.[27]

Most of the increase in U.S. manufacturing S/E personnel should be in durable goods. (See figure 3-20.) While employment in non-S/E occupations in this division is projected to decline slightly over the 12-year period, S/E jobs are expected to rise by 256,000, or 32 percent. (See figure 3-21.) Nondurable goods industries are projected to lose a substantial number of non-S/E jobs, even as growth in output continues at or higher than current rates. Due to occupational restructuring, however, S/E employment in these industries should increase by about 17 percent.

[27]Hirschhorn (1987), p. 9.

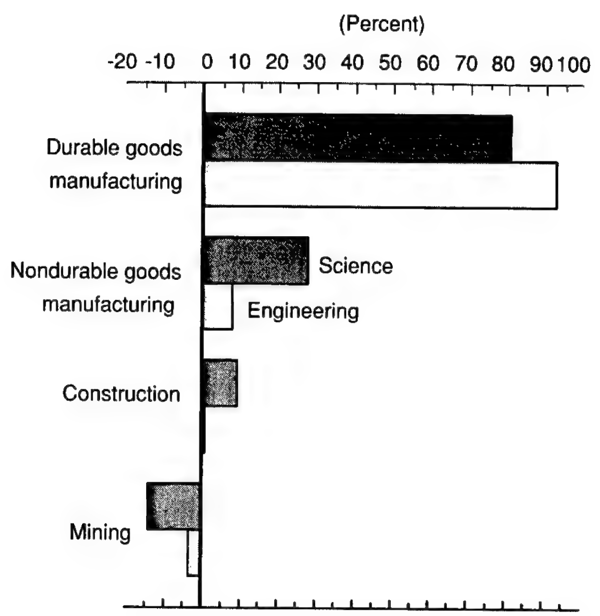
Figure 3-20.
Distribution of new S/E jobs to be created in goods-producing industries: 1988-2000



See appendix table 3-1. *Science & Engineering Indicators—1989*

Occupations

During the 1988-2000 period, the occupational composition of industry jobs is expected to change, shifting away from production and assembly-line jobs toward professional, managerial, and technical occupations. Thus, while industry as a whole is expected to provide approximately 9 percent more jobs between 1988 and 2000, employment opportunities for S/E jobs are projected to increase by about 34 percent. The disproportionate rise in S/E jobs will result from general requirements for a higher proportion of workers with more education than in the past, and because the need to remain competitive will require an increasing number of S/E workers to update product designs, explore more cost-effective technology for producing goods, and develop new products.[28]

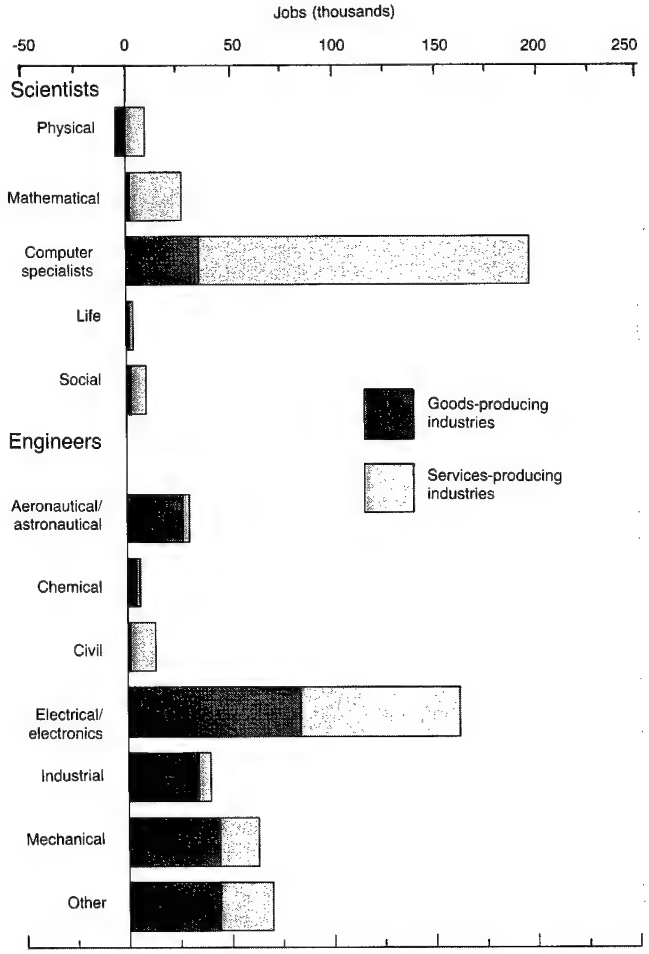
The S/E occupation benefitting most from these trends has been, and should continue to be, that of computer

[28]For an excellent discussion of the economic factors affecting occupational pattern changes, see Silvestri and Lukasiewicz (1987). Also see Personick (1987).

specialist. This occupation is expected to have the largest employment gain (197,000 jobs) and the fastest growth (62 percent) of any S/E occupation. (See figure 3-22.) About half of the employment gain for computer specialists is projected to occur in the business services division, primarily in computer and data processing services. The remaining increase should be spread throughout industry, as computers continue to be used more intensively by more industrial employers. New business and defense applications are expected to continue to be primary sources of requirements for computer specialists.

The electrical/electronics engineering occupation is projected to have the next biggest absolute employment gain, up by 162,000 jobs or by nearly 40 percent. This increase is expected to be divided almost equally between the goods- and services-producing sectors, with increases of 84,000 and 78,000, respectively. These engineering jobs should be primarily in the manufacturing industries producing communications equipment, computers, and other electronics equipment, and in the engineering and architectural firms servicing these industries.

Figure 3-22.
Projected change in number of S/E jobs in private industry, by occupation and sector: 1988-2000



See appendix table 3-1. *Science & Engineering Indicators—1989*

S/E SUPPLY OUTLOOK

Stock and Flow of the S/E Labor Market

The flows of scientists and engineers into and out of the S/E workforce are highly complex due to the many forces affecting them. Additionally, there is a lack of concurrent and comparable data on all of the segments comprising new supply to and attrition from S/E employment. To approximate the magnitudes of S/E flows and their relative contributions to the overall stock of scientists and engineers, data from several different sources and time periods have been used and certain judgments exercised. No attempt is made here to infer current or future supply/demand relationships from these data, but rather to illustrate the relative magnitudes of these flows—insofar as possible—from the historic data available.

These flows are highly sensitive to such factors as:

- S/E supply/demand conditions, including economic growth;
- Defense and R&D spending;
- The population demographics, interest, and capabilities affecting the number of new entrants and attrition from the stock;
- Legislation and policy affecting the entry of foreign students and immigrants; and
- Policies and laws regulating retirement ages, etc.

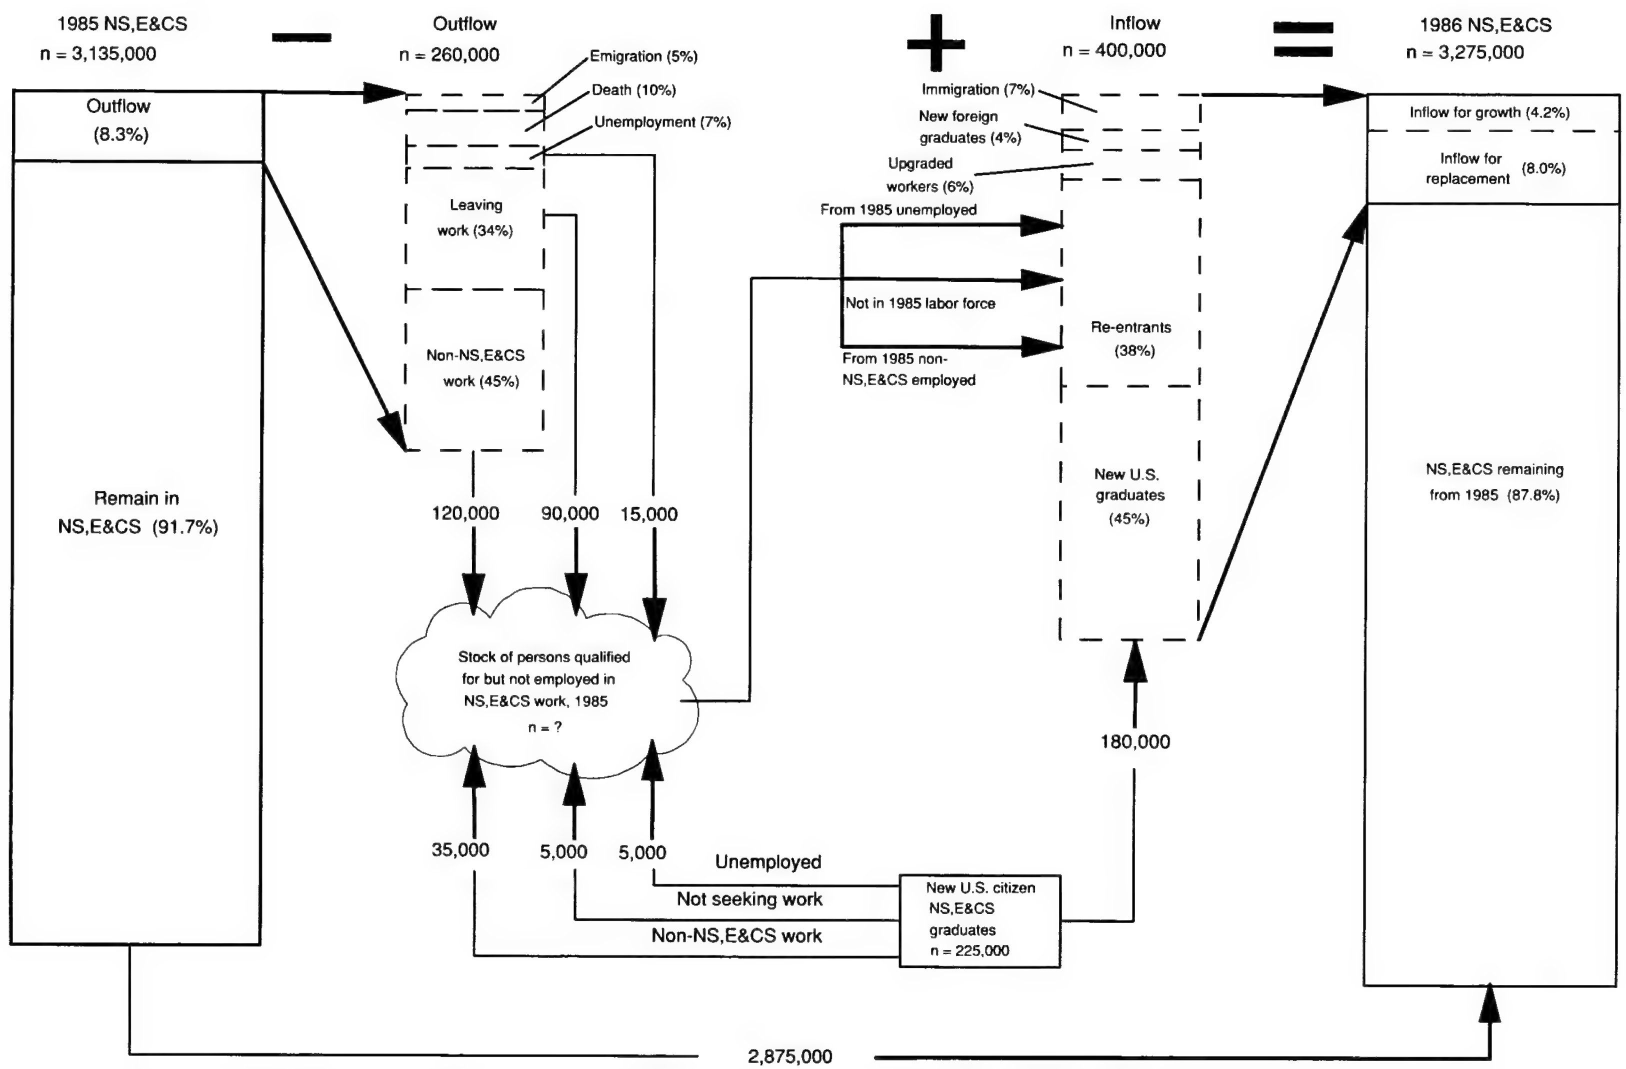
The data in figure 3-23 are illustrative of the relative importance and magnitudes of the stock and the various flows. For this analysis, the most recent available estimates of the various stocks and rates of inflows and outflows are used to approximate the dynamics of change in the overall stock of natural scientists, engineers, and computer specialists (NS,E&CS) between 1985 and 1986.[29]

The stock of employed natural scientists, engineers, and computer specialists in 1986 reflected:

- Those who remained in NS,E&CS employment from the previous year—about 92 percent of the 1985 total;

[29]Comparable estimates for social and behavioral scientists are shown on appendix table 3-12. Unpublished tabulations by BLS from the 1985 and 1986 Current Population Surveys and the 1986 Occupational Employment Statistics survey were used to develop estimates of the stock of persons employed in S/E occupations. For more information on these surveys, see U.S. BLS (1982). Elsewhere in this chapter, 1986 data are presented on the characteristics of persons who are classified as scientists or engineers based on their education and experience. These data are not strictly comparable with the information in this section, which describes S/E occupational patterns.

Figure 3-23.
Estimated changes in NS,E&CS stock and flow: 1985-86



Notes: NS,E&CS = employed in natural science, engineering, and computer specialist jobs. Absolute numbers rounded to nearest 5,000.
See appendix table 3-12.

Science & Engineering Indicators—1989

- Outflows of workers who left NS,E&CS employment, i.e., those who left the labor force, switched occupations to non-NS,E&CS employment, became unemployed, died, or emigrated—about 8 percent of the 1985 total; and
- Inflows from persons who re-entered NS,E&CS work, recent graduates who took NS,E&CS jobs, technicians and other skilled workers who upgraded to or obtained NS,E&CS positions, and foreign scientists and engineers.

Between 1985 and 1986, it is estimated that about two-thirds of such inflows were required to replace workers who left NS,E&CS employment; the remaining one-third covered the growth in NS,E&CS jobs that stemmed from economic expansion, increased military expenditures, greater technological intensity, additional R&D, et al.

Outflows From NS,E&CS Employment. The total estimated outflow during 1985 from the employed NS,E&CS workforce was about 8 percent of those employed as natural scientists, engineers, and computer specialists at the beginning of the year. The remaining 92 percent of the NS,E&CS workers stayed in NS,E&CS work and comprised the bulk of the NS,E&CS workforce the following year.

Of the 8 percent of the workers who left NS,E&CS employment, the largest outflow—over two-fifths—was of persons changing to non-NS,E&CS occupations, followed by persons exiting the labor force (e.g., retirees, those returning to school, those choosing to stay at home to rear children, etc.)—about one-third. The remainder of the outflow included aliens previously admitted to the U.S. and naturalized citizens who emigrated, those who became unemployed, and those who died.[30] Each of these groups (except the last) represents a possible source of re-entrants to the NS,E&CS workforce.

[30]*Attrition* out of the labor force (except for death and emigration) was calculated by applying occupation-specific separation rates for the 1983-84 period. See U.S. BLS (1986), table C-1. *Annual transfer rates* to non-NS,E&CS occupations were estimated from longitudinal survey data of scientists and engineers in the 1980 population by their occupational status in 1982 and 1984 from tabulations of unpublished NSF data prepared by Dr. Robert Dauffenbach, Oklahoma State University. The transfer rates do not include persons who transferred to manager/administrator jobs if these were related to the management or administration of NS,E&CS activities. The transfer rates also do not apply to transfers among NS,E&CS fields, but only out of the total NS,E&CS workforce. *Annual death rates* by sex and age are from estimates for the population by the Bureau of the Census for the 1985-90 period applied to NSF distributions of scientists and engineers by age and sex. The "Low Mortality Assumption" table was used to account for differences in racial mix and type of employment between the general population and NS,E&CS workers. See U.S. Bureau of the Census (1984), table B-1A. *Unemployment* does not include the stock of unemployed in 1985, but only the net change in unemployment from 1985 to 1986. Unemployment rates are from unpublished BLS occupation-specific data. See U.S. BLS (1986). *Emigration rates* were estimated separately for naturalized U.S. citizens and aliens. The rates are derived from estimates of average emigration for the 1981-85 period. See Finn and Clark (1988). The estimates for emigration assume that there is no net emigration of natural-born citizens. The data on *alien S/E admissions* are from the U.S. Immigration and Naturalization Service.

Inflows to NS,E&CS Employment. Entrants are needed to fill the new NS,E&CS jobs created by economic growth and the increasing demand for NS,E&CS personnel. In addition, replacements must be found for people who leave the workforce. About 260,000 of those employed as natural scientists, engineers, and computer specialists left the NS,E&CS workforce between 1985 and 1986. Analysis of the 1986 stock shows that, besides the replacements needed for this outflow, an additional 140,000 people were hired to fill the approximately 5-percent increase in total NS,E&CS jobs created between 1985 and 1986. The total estimated NS,E&CS inflows of 400,000 are equivalent to about 12 percent of the 1986 NS,E&CS stock of 3.3 million.

New U.S. citizen NS,E&CS graduates were the largest component of the total inflow to the 1986 stock, approximately 45 percent.[31] The second largest portion of the inflow, 38 percent, consisted of re-entrants to the NS,E&CS workforce of scientists and engineers who were doing non-NS,E&CS work or who were temporarily out of the labor force.[32] The recent foreign graduates of U.S. colleges and universities and direct immigration of experienced foreign NS,E&CS together accounted for about 10 percent of the inflow.[33] About 5 percent of the inflow were estimated to be persons who were upgraded to engineering jobs.[34]

[31]The estimates for new bachelor's and master's degree graduate entrants are from NSF (1987); the estimates for new Ph.D. recipients are from NSF (1988d). The data for new bachelor's and master's degree recipients are for the labor force status in 1986 of 1985 graduates who were not full-time graduate students in 1986. The data exclude foreign students who had a foreign address at the time of the survey.

The labor force entrance rates for the 1985 graduates were adjusted upward, based on the status of 1984 graduates in 1986. The longer postgraduation lag time was used to provide a more realistic estimate of the contribution of recent graduates to the NS,E&CS workforce, since participation rates increase substantially between the first and second year after leaving school. The data were also adjusted for an estimate of double counting of master's degree recipients and Ph.D.s who may already have been employed in NS,E&CS jobs while in graduate school. Downward adjustments for Ph.D.s were made for those reporting their major source of support in graduate school as teaching or research assistantships, employer funds, or own earnings. The rates for employer funds and own earnings for Ph.D.s were applied to the master's new entrants, as such data are not collected for them.

All bachelor's new entrants were assumed to be first-time entrants. The aforementioned surveys of new entrants do not include those receiving the bachelor's of technology degree. An estimate for bachelor's of technology degree recipients who became NS,E&CS workers was calculated by assuming the same labor force participation rates as for engineering bachelor's degree recipients and applying that rate to the 19,600 technology degrees awarded in 1985. The resulting 16,600 new entrants are included in the inflow to the NS,E&CS workforce.

[32]This proportion is the remainder of the inflow requirements for growth and replacement after accounting for the inflows of new graduates, immigrants, and worker upgrading.

[33]Estimates for foreigners receiving U.S. bachelor's and master's degrees are from flow rate estimates for 1981-82 from Finn (1985). Data for foreigners with U.S. Ph.D.s are for 1985 from NSF (1988d).

[34]In 1982, there were about 171,000 persons employed as engineers without a bachelor's degree, or roughly 16.3 percent of the employed engineering workers. See NSF (1984). These persons are loosely designated as "upgraded workers." It is assumed that upgrading to engineer status for meritorious non-degreed persons from among the nearly 1 million engineering technicians and other persons with S/E training would continue at about the same rate so as to maintain their share of total engineering jobs.

The 180,000-person inflow of new U.S. citizen NS,E&CS graduates between 1985 and 1986 was greater than the 140,000-person increase in total NS,E&CS jobs created during this period. The difference (40,000) is the amount that the total outflow from 1985 exceeded the total inflow to the 1986 stock, excluding new graduates.

The Stock of Possible NS,E&CS Re-Entrants. As noted above, almost 40 percent of the inflow to the 1986 NS,E&CS stock were re-entrants to the employed NS,E&CS workforce. Included in this group are:

- Natural science, engineering, and computer science graduates[35] who had delayed entering the labor force, even though they are not, strictly speaking, re-entrants;
- NS,E&CS personnel who were employed in non-NS,E&CS jobs in 1985; and
- Other NS,E&CS personnel who had not worked in that year, including retirees from NS,E&CS employment and those who temporarily left the labor force for child rearing or other reasons.

The size of this group cannot be estimated reliably. There are substantial numbers of persons of working age with formal training in science and engineering who are not employed in NS,E&CS occupations. For example, in the 25 years between 1961 and 1986, 3.9 million bachelor's degrees in the natural sciences, engineering, and computer science were awarded in the United States, or roughly 800,000 more than the number of persons employed in NS,E&CS occupations. However, the ability of this group to meet exigencies of possible future shortfalls in the supply of new entrants is not known. The propensities of entry to NS,E&CS jobs would vary substantially depending upon the level of NS,E&CS training and experience held by these persons, their age, their attachment to their current employment or other labor force status, how long they have been away from NS,E&CS work, and on labor market conditions affecting employers' willingness to hire or retrain such qualified persons or to pay sufficient wages to attract qualified potential re-entrants from high-paying positions outside the NS,E&CS workforce.

Further—to the extent that the stock of potential NS,E&CS re-entrants does not match workforce requirements by occupation, skills, or experience—the ability to supply needed workers will be limited. This group merits further study to address its contribution to the NS,E&CS workforce.

Summary. The following summarizes the major points of this analysis of the stock and flow of natural scientists, engineers, and computer specialists between 1985 and 1986.

- Over the 1-year period of time, the stock was over 10 times as large as the flow. A little more than 8 percent of the 1985 NS,E&CS workforce left and just over 12 percent of the 1986 NS,E&CS were new or re-entrants.
- The most important factors in the estimated 1985 outflow were those moving to non-NS,E&CS work (over two-fifths) and those leaving work (over one-third). Each of the other factors—death, unemployment, emigration—accounted for one-tenth or less of the outflow. Since the total outflow was less than 9 percent of the total stock, this means that each of these three other outflow factors accounted for between about 0.3 percent and 0.8 percent of the estimated 1985 stock.
- About two-thirds of the NS,E&CS inflows were used to replace outflows, while the other one-third was used for the growth in NS,E&CS employment. The most important factors in the estimated inflows to the 1986 NS,E&CS were new U.S. citizen graduates (about 45 percent) and re-entrants (about 40 percent). Each of the other factors—worker upgrades, immigration, and new foreign graduates—accounted for 7 percent or less of the inflow. As the total inflow was only about 12 percent of the total stock, this means that each of these latter three inflow sources accounted for between about 0.4 percent and 0.9 percent of the estimated 1986 stock.

The acknowledged lack of statistical precision in procedures used to estimate some of the minor factors in this section have relatively little effect on the results, as shown by some sensitivity testing. If, for example, the estimate for worker upgrades (admittedly a difficult number to estimate given current data) is off by as much as ±50 percent, the relative impact of this group on the 1986 stock would be between 0.4 percent and 1.1 percent—i.e., (25,000 ± 12,500)/3,275,000. Similarly, the other, smaller factors for which estimates incorporating judgment had to be used would have minor impact even if a range of ±50 percent were used to sensitivity-test the effect of the estimating procedures.

Given the high degree of stability of the stock of NS,E&CS employed and the demonstrated availability of multiple sources of supply, it is clear that substantial adjustments to changing supply and demand conditions in the NS,E&CS labor market are possible. The major remaining questions about such adjustments are their costs (in terms of time and resources), whether they would be sufficient to meet a sustained increase in demand, and how the quality of NS,E&CS personnel would be affected.

Outlook

As long as the Nation maintains a vigorous economy, spot shortages and surpluses in some S/E fields seem to be unavoidable, as typified by recent shortages in some engineering subfields and computer specialties. While market forces generally have been able to remedy such imbalances in the past, future corrective actions may require increased or new Federal policy measures. To meet the anticipated increase in demand for S/E personnel in the 1990s, several adjustments may have to occur because:

[35]For purposes of this analysis, recent graduates who are full-time graduate students are not included in the potential pool since estimates of their post-school employment status are made after they leave school.

- The size of the traditional 18- to 24-year-old college-age cohorts will decline through the early 1990s, and
- Retirements may increase due to larger proportions of experienced S/E workers reaching 55 or older.

Shortages may not necessarily develop. Some of the gap may be filled by increased enrollment of the 18- to 24-year cohort as well as older students and foreigners, many of whom remain to work in the United States. In addition, small shifts in the percentages of students choosing to train in S/E fields, and in the proportions of graduates who choose to enter S/E employment fields, could provide an adequate supply of new entrants to the S/E workforce.[36]

There are other adjustments that can also occur. Labor force mobility is particularly important in instances of tight markets when newly trained S/E entrants and S/E personnel in the experienced pool may be induced to leave their current fields of specialization and transfer into higher demand fields. This is what occurred in satisfying the very high growth in demand for computer specialists. There may also be fewer S/E-trained people attracted to non-S/E jobs. Additionally, there may be delays in retirements of S/E workers in response to needs for their services; this has been the case in past engineering shortages. Finally, employers may provide training and upgrading of technician personnel.

What is uncertain is the magnitude of these possibly required adjustments. Past experience indicates that these supply movements, together with adjustments made by employers, have been generally sufficient to meet the growing demand for S/E personnel;[37] projecting ahead, however, is much more complex. For example, although it is known that women, ethnic minority, and older students are a rising proportion of all undergraduates, it is uncertain how many of them will enter S/E employment fields. Also, while it is believed that adjustments in enrollment patterns will be made in response to a growing demand for S/E graduates, it is not clear that any adjustments will be sufficient to provide an adequate supply in the future. Further, many of the adjustments noted above could entail substantial costs and possibly affect the quality of the S/E workforce.

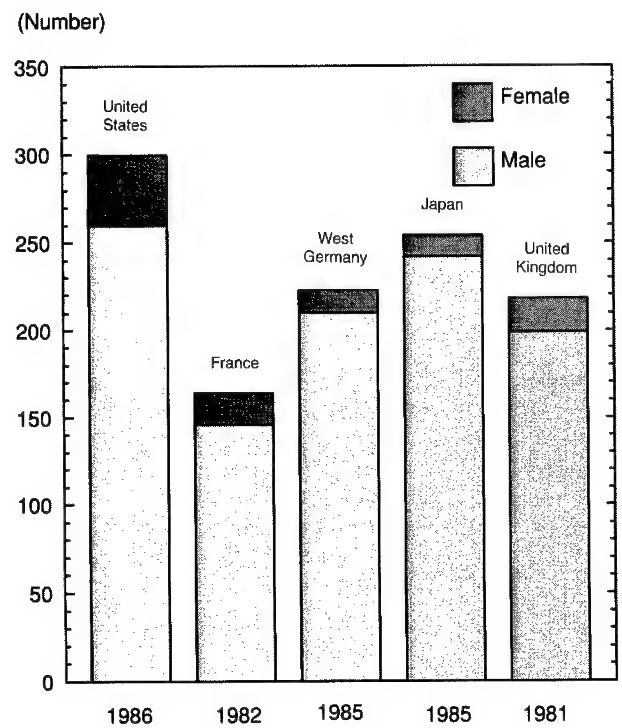
INTERNATIONAL EMPLOYMENT OF SCIENTISTS AND ENGINEERS

The employment of scientists and engineers is a significant indicator of the level of effort and relative national priority for science and technology among major industrial countries. While problems of comparability exist because of differences among countries in their methods of data collection and estimation, international employment data provide meaningful insight into the relative strengths of the S/E workforces in the United States and other countries.

In the early to mid-1980s, the number of nonacademic scientists and engineers employed in the United States exceeded the combined total of those in France, West Germany, Japan, and the United Kingdom. This result was not unexpected, because the total U.S. population is about the same as that of the other countries combined. Examining the number of scientists and engineers as a proportion of each country's total labor force showed that the United States employed the highest percentage of scientists and engineers, followed closely by (in descending order) Japan, West Germany, the United Kingdom, and France. (See figure 3-24.) In all countries examined, service industries predominated among employers of scientists, while manufacturing industries employed the largest proportions of engineers.

In the United States and Japan, a quarter of the scientists and engineers employed in manufacturing industries in the early to mid-1980s were electrical/electronics engineers. Manufacturing industries in France employed relatively more civil engineers than in the other countries; West Germany employed a relatively greater proportion of natural scientists. A much higher proportion of Japan's

Figure 3-24.
Nonacademic scientists and engineers per 10,000 labor force for selected countries, by gender



See appendix table 3-13. *Science & Engineering Indicators—1989*

[36]Hansen (1986).

[37]For instance, a recent report from the National Research Council concluded that, since 1972, a substantial portion of job openings for engineers has been filled from pools other than the traditional supply source of new U.S. citizen engineering recipients, and that the supply of engineering talent has, therefore, been capable of adjusting to wide swings in employment. See NRC (1988), pp. 37-38.

scientists and engineers were employed in service and construction industries, while scientists and engineers in the United States were more evenly divided between manufacturing/mining industries and service industries. In France, a very high percentage of scientists and engineers worked in the government sector. (See figures 3-25 and 3-26.)

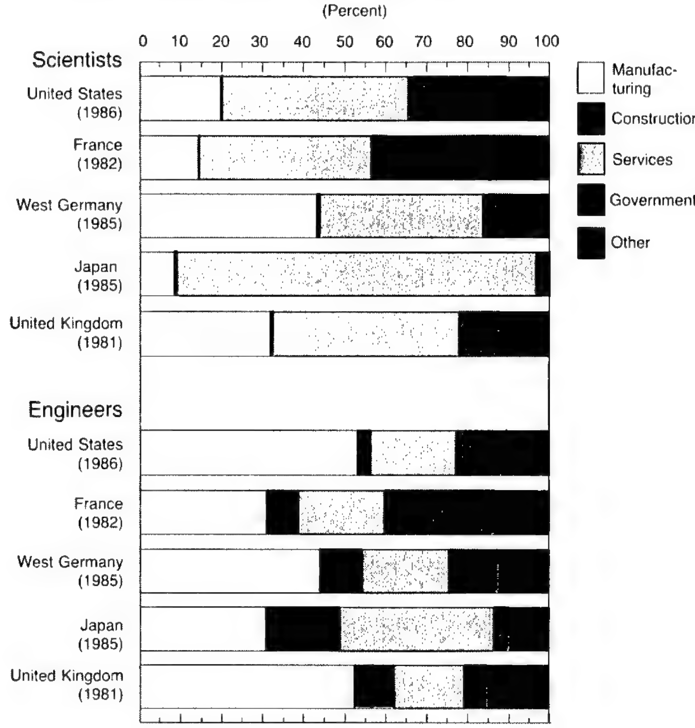
In absolute terms, the United States has the largest number of scientists and engineers working in R&D of any country. (See figure 3-27.) As a proportion of the labor force, however, other countries now have concentrations of R&D scientists and engineers approximating that of the United States. In 1986, Japan's ratio per 1,000—6.74—was nearly identical to that of the United States—6.62.

The United States led the United Kingdom in the number of scientists per 1,000 total labor force (12 versus 8 per 1,000) and was second to Japan in the number of engineers per 1,000 labor force (18 versus 19 per 1,000) in the early 1980s. However, the U.S. ranked first among the countries compared in the ratio both of scientists and of engineers with university degrees.[38] In West Germany, most engineers have qualifications from technical colleges.[39] Of the reported scientists and engineers in the United Kingdom, less than half have a university degree. Nonetheless, some of these countries may have stronger training in science and mathematics at the precollege level.

[38]Way and Jamison (1986), p. 2.

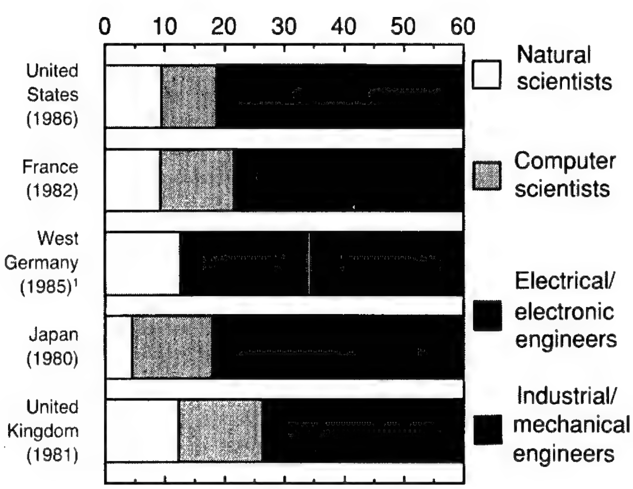
[39]For comparability, only engineers with university degrees are used for comparisons. West German engineers trained in professional colleges generally have received more specialized and technically intensive training; university degree recipients have received broader and more academic engineering training.

Figure 3-26.
Nonacademic scientists and engineers in selected countries, by sector of employment



See appendix table 3-15. *Science & Engineering Indicators—1989*

Figure 3-25.
Scientists and engineers in manufacturing for selected countries, by occupation group

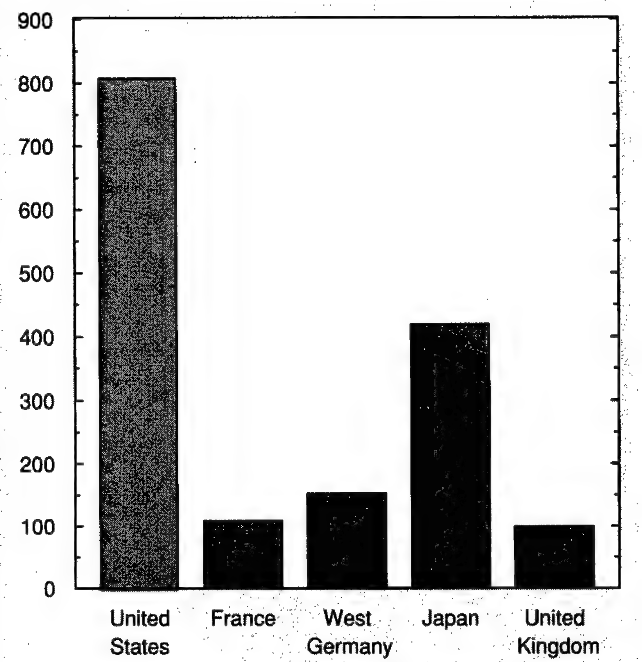


¹Computer scientists are included under natural scientists as well as electrical/electronic engineers.
See appendix table 3-14. *Science & Engineering Indicators—1989*

The United Kingdom, France, and West Germany all had a greater concentration of first university degrees in the natural sciences in 1986 than did the United States. (See figure O-7 in Overview.) In absolute numbers, however, the U.S. degree recipients were more numerous. In 1982, Japan graduated more engineers at the bachelor's level than did the U.S., but by 1983, the number of U.S. engineering graduates was 5 percent greater due to an 8-percent increase in the number of U.S. graduates and a 5-percent drop in Japanese engineering degrees. The U.S. awards more than twice the number of engineering doctoral degrees and more than 10 times the number of natural science doctorates than does Japan.

The age of a country's S/E labor force can be an indicator of the recency of training and its future capabilities. Japan had the youngest scientists and engineers of the five countries, including the United States: in 1985, almost half of the Japanese nonacademic scientists and engineers were under 35 years old, and only 7 percent were 55 or older. This supports recent observations about the high output of the Japanese educational system. About half the scientists and engineers in France, West Germany, and the United States were between 35 and 54 years old. (See figure

Figure 3-27.
Scientists and engineers engaged in R&D for selected countries: 1987



Note: United States and United Kingdom data are for 1986, all others are 1987.
See appendix table 3-16. *Science & Engineering Indicators—1989*

Figure 3-28.

See appendix table 3-17. *Science & Engineering Indicators—1989*

3-28.) On average, women scientists and engineers were younger than their male counterparts in all countries.

When all five countries were compared, the vast majority of engineers were men, with the small proportion of females slowly increasing. Science occupations also were predominantly male, but with a larger percentage of women represented. The United States, France, and the United Kingdom had the best records of using female scientists and engineers (10 percent). Only 6 percent of scientists and engineers in West Germany were women; nearly half of these were social scientists. In Japan, women comprised only 5 percent of the scientists and engineers. Nearly half of these women were computer scientists.

Chapter 4
Financial Resources for Research and Development

CONTENTS

Financial Resources for Research and Development

HIGHLIGHTS

The Nation's investments in research and development (R&D) have continued to grow.

- *Total R&D investments are estimated to have increased by 44 percent since 1980 (in constant dollars), compared with an increase of 17 percent in the previous decade.* The estimated 1989 national investment reached $132 billion, or 2.6 percent of the gross national product (GNP). (See p. 87.)
- *In recent years, the rate of increase in these R&D investments has slowed.* From 1981 to 1985, total national expenditures for R&D averaged 6-percent growth per year, in constant 1982 dollars, in contrast to an estimated 2-percent annual growth between 1985 and 1989. Only R&D performed at academic institutions shows a high growth rate since 1985. (See p. 87.)

Except in the academic sector, patterns in R&D funding and performance have changed little in the 1980s.

- *During the 1960s and 1970s, Federal R&D funding decreased relative to industry funding.* But since 1980, Federal and industry shares have remained steady and about equal, at about 47 percent for the Federal share compared with an industrial share of about 48 percent. (See pp. 87-88.)
- *From 1980 to (estimated) 1989, Federal nondefense obligations declined 3 percent.* While Federal obligations for nondefense basic research increased 51 percent over the decade, cutbacks in development (-34 percent) and applied work (-10 percent), largely related to energy technologies, account for the net decline in nondefense Federal R&D obligations. (See p. 94.)
- *In the performance of R&D activities, relative sectoral shares have remained stable.* Private firms perform about 72 percent of total national R&D, universities about 11 percent, and the Federal Government about 11 percent. (See p. 88.)
- *In constant dollars, academic institutions have doubled investments of their own funds in R&D since 1980.* Academic institutions received Federal support for 59 percent of their R&D activities in 1989, down from 68 percent in 1980. As a percentage of the total R&D performed by this sector, the institutions' own funds grew from 22 percent to 27 percent over the same period, and industrial funds from 4 percent to 7 percent. (See pp. 88-89.)
- *In constant dollars, performance of R&D by industrial firms reflects aggregate national R&D patterns.* From 1980 to 1985, firms' R&D performance grew at about 5 percent annually; since 1985, this growth has slowed to less than 2 percent annually. (See p. 87.)

R&D investment priorities differ considerably among the industrialized countries.

- *The U.S. spends more on R&D than the United Kingdom, Japan, France, and West Germany combined.* (See pp. 3, 96.)
- *Japan and West Germany both invested a larger percentage of their 1987 GNPs in R&D (2.9 percent and 2.8 percent, respectively) than did the U.S. (2.6 percent).* Japan has now exceeded the U.S. on this indicator for 3 years (1985-87). (See p. 96.)
- *Japan, West Germany, France, and the United Kingdom combined invested $11 billion more than the U.S. in nondefense R&D.* Relative to GNP, Japan invested a percentage point more in nondefense R&D than the U.S. in 1987, and Japan's growth on this indicator has been rapid. Between 1979 and 1987, the U.S. increased its nondefense R&D/GNP ratio from 1.6 to 1.8, compared to increases for Japan of 2.0 to 2.6, for West Germany of 2.1 to 2.6, and France of 1.4 to 1.8. (See pp. 96-97.)
- *West Germany invested 15 percent of its total governmental R&D in industrial development, compared to less than 1 percent in the United States.* Japan invests heavily in energy-related R&D compared to the U.S.—23 percent versus 4 percent. (See p. 97.)
- *Among broad fields of academic R&D, the U.S. invests by far the largest proportion in the life sciences (49 percent), followed by 16 percent in the physical sciences and 13 percent in engineering.* In these same fields, Japan invests 34 percent, 15 percent, and 22 percent, respectively, of its total academic R&D. (See pp. 98-99.)

In response to shifting economic conditions and other factors, states have increased their support of science and technology (S&T) activities.

- *Funding of R&D from the states' own funds has more than doubled since 1977, reaching about $769 million in 1988.* The states are involved in a variety of activities in support of S&T, from research grant programs to provision of venture capital for company start-ups. However, total state funding of R&D from the states' own sources accounted for less than 1 percent of national R&D expenditures. (See pp. 101-102.)

This chapter discusses financial indicators of the Nation's research and development (R&D). The first section describes broad patterns in the funding and performance of R&D both in the current period and over the longer term. The patterns of interest are flows of financial resources among science and engineering (S/E) funding and performing institutions in the various sectors.[1]

The second section narrows the focus from total national R&D funding and performance to a consideration of the *character* of these activities—i.e., basic research, applied research, and development. Transfers of funds among R&D-funding and -performing sectors (government, academia, industry, and nonprofit institutions) show differing patterns for each sector across the various R&D activities and broad fields of science and engineering. Section three provides comparisons on similar R&D topics among the major industrialized countries.

A new, final section in this chapter presents indicators of support for science and technology (S&T) on the state level. A recent survey of state S&T funding agencies generated data on state agency expenditures for R&D, and these data are compared with those from the last such survey in 1977. The section also contains indicators of institutional development in the support of state-level S&T programs, and a discussion of the different types of programs these agencies use to foster S&T-based economic development.

NATIONAL R&D FUNDING PATTERNS

In 1989, the United States spent approximately 2.6 percent of its gross national product (GNP) on R&D activities, according to current estimates. This investment in the discovery of new knowledge—and in the application of knowledge to the development of new products, processes, and services—totaled an estimated $132 billion.[2]

This section discusses broad patterns in the Nation's R&D investment—specifically, patterns among R&D funders and performers, among the standard classifications of R&D work (basic, applied, and development), and across various governmental socioeconomic objectives, including defense- versus nondefense-oriented R&D.

Long-Term Trends

In constant 1982 dollars, the Nation's R&D expenditures have more than doubled over the past three decades, rising from about $44 billion in 1960 to an estimated $105 billion in 1989. (See appendix table 4-2.) Considerable structural changes in the patterns of R&D support and performance have accompanied this real expansion of R&D investment.

The most notable of these changes concerns the relative roles of the Federal Government and private industry in *funding*, or supporting, R&D. The Federal share of total national R&D expenditures has fallen steadily, dropping from 65 percent in 1960 to an estimated 47 percent in 1989. (See appendix table 4-2.) Over the same period, U.S. firms have increased their relative share of support for total U.S. R&D activities from 33 percent to 48 percent. This includes both in-house R&D and funding of R&D in other sectors. Also, university and college support for R&D grew over the three decades, rising from 1 percent to 3 percent of the national total. This growth in relative share has been even more pronounced in basic research.

R&D *performance* patterns have also changed, but in different ways. In contrast to their overall increased support for R&D, private firms are estimated to have performed a smaller share of R&D in 1989 than in 1960: 72 percent versus 78 percent, respectively. Research universities and colleges increased their share of R&D performance from 5 percent to 11 percent of the national total over the same period. This growth in R&D performed on the Nation's campuses has resulted from steadily rising sponsorship of R&D work by both the Federal Government and private industry, and from increased investments by the institutions themselves.[3]

Recent Trends

National investment in R&D generally rose in the 1980s—4 percent annually on the average. This growth has slowed during recent years, however. (See figure O-19 in Overview.) Compared to an average annual constant-dollar increase of over 6 percent in total national expenditures for R&D between 1981 and 1985, expenditures between 1985 and 1989 are estimated to grow only 2 percent per year. Industry's funding of its own R&D has slowed considerably, from average annual growth rates of 5 percent in the first half of the decade to an estimated less than 2 percent in the second half. (See appendix table 4-2.) Growth in Federal *in-house* R&D virtually halted over the past 4 years, down from increases of almost 7 percent per year between 1981 and 1985.

Only R&D performed by academic institutions continued to grow strongly throughout the decade, actually increasing its growth rates since 1985 to a 6-percent annual average.

1989 Patterns

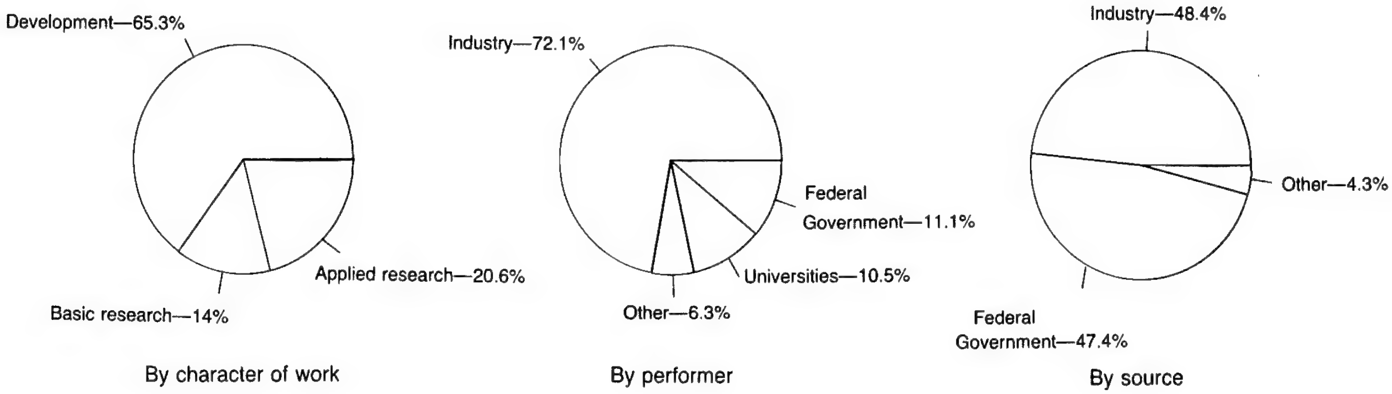
Funds for R&D in the United States came mainly from two sources in 1989—private firms and the Federal Government. (See figure 4-1.) U.S. businesses used their own funds to finance 48 percent of the Nation's total investment in R&D; the Federal Government provided 47 percent. (See

[1]Most of the data in this chapter are financial data, and changes in expenditures are taken as indicators of real changes in the amounts of S/E being funded and performed in the Nation. Since no single unit of new knowledge exists, funding and expenditure data *measure* monetary transfers among R&D-funding and -performing institutions, but only *indicate* changes in the "amount" of R&D being supported and performed. By necessity, then, this chapter discusses *science* as a process or activity; it does not discuss the results of this activity. See chapter 5 for other indicators of scientific processes and chapters 6 and 7 for S/E output indicators.

[2]Throughout this chapter, current funding or expenditure data are presented in current dollars. Trend data are usually deflated to 1982 constant dollars using the GNP implicit price deflator, and are identified as such. See appendix table 4-1.

[3]See chapter 5 for other indicators of these trends.

Figure 4-1.
National R&D expenditures: 1989



See appendix tables 4-2, 4-3, 4-4, and 4-5.

Science & Engineering Indicators—1989

text table 4-1.) The remainder of 1989 R&D funding came from universities and colleges and nonprofit institutions.

The role of private industry is larger in *performing* R&D activities than in *funding* them. In 1989, the estimated $95 billion in R&D performed by firms accounted for 72 percent of total national R&D performance. One-third of this was financed by the Federal Government. (See appendix table 4-2.) During the 1980s, Federal financing of R&D performed by industry increased at an average annual rate of 5 percent; however, this growth rate has slowed to less than 2 percent per year since 1985 (in constant 1982 dollars). Most of the strong growth in Federal Government support for R&D in industry during the past decade was accounted for by the Federal defense budget (discussed further below).

Total Federal expenditures for R&D reached an estimated $63 billion in 1989. (See text table 4-1.) Of this,

- 52 percent was transferred to industry,
- 25 percent was disbursed to various Federal agencies,
- 14 percent to universities and colleges,
- 8 percent to federally funded research and development centers (FFRDC), and
- 1 percent to nonprofit institutions. (See appendix table 4-2.)

The third largest R&D-performing sector consists of the Nation's universities and colleges.[4] These institutions depended on Federal funds for an estimated 59 percent of their R&D activities in 1989; this is down from 67 percent

[4]One hundred universities account for about 85 percent of the R&D performed by this sector. The research activities of these institutions are discussed more fully in chapter 5.

Text table 4-1. U.S. R&D funders and performers: 1989

Funders	Millions of dollars	Percent	Performers	Millions of dollars	Percent
Industry	64,035	48	Industry	95,350	72
Federal Government	62,700	47	Federal Government	14,750	11
Universities and colleges	3,800	3	Universities and colleges	13,900	11
			FFRDCs	4,650	4
Nonprofits	1,815	1	Nonprofits	3,700	3
Totals	132,350	100		132,350	100

Notes: Data are estimates. See footnotes appendix table 4-2.

See appendix table 4-2.

Science & Engineering Indicators—1989

Definitions

The National Science Foundation (NSF) uses the following definitions in its resource surveys.

Basic research: Basic research has as its objective a fuller knowledge or understanding of the subject under study, rather than a practical application thereof. As applied to the industrial sector, basic research is defined as research that advances scientific knowledge but does not have specific commercial objectives, although such investigations may be in fields of present or potential interest to the reporting company.

Applied research: Applied research is directed toward gaining knowledge or understanding necessary for determining the means by which a recognized and specific need may be met. In industry, applied research includes investigations directed to the discovery of new scientific knowledge having specific commercial objectives with respect to products or processes.

Development: Development is the systematic use of the knowledge or understanding gained from research directed toward the production of useful materials, devices, systems, or methods, including design and development of prototypes and processes.

Obligations: Obligations represent the amounts for orders placed, contracts awarded, services received, and similar transactions during a given period, regardless of when the funds were appropriated or when payment is required.

in 1980. (See appendix table 4-2.) Academic institutions themselves finance a larger proportion of their R&D—from 22 percent in 1980 to an estimated 27 percent in 1989. Similarly, transfers from industry to universities and colleges have increased over the same period—from 4 percent to 7 percent of the total R&D performed in these institutions.[5]

BASIC RESEARCH, APPLIED RESEARCH, AND DEVELOPMENT

Each of the sectors fund and perform basic research, applied research, and development to varying degrees. (See "Definitions," this page.) Different sectors dominate in these R&D work categories:

- Industry in both *funding* and *performing* development and applied research,
- The Federal Government in *funding* basic research, and
- Research universities in *performing* basic research.

The following sections discuss patterns and emphases by character of work among these sectors and other funders and performers of R&D.

Broad National Patterns

While the Nation's total investment in R&D has grown significantly, the relative emphasis of this investment among basic and applied research and development has changed hardly at all. Since 1960, the proportions of total R&D devoted to these types of activities have shifted only marginally:

- Development has fluctuated between 63 percent and 69 percent;
- Applied research, between 21 percent and 24 percent; and
- Basic research, between 9 percent and 14 percent. (See appendix tables 4-2, 4-3, 4-4, and 4-5.)

In 1989, private firms performed 85 percent of *development*, followed by Federal in-house laboratories, which performed 11 percent. (See figure 4-2.) Firms also performed most of the *applied* work (72 percent); the academic sector and Federal in-house laboratories were each responsible for 12 percent of the total. Half of the *basic* research was performed by universities and colleges; of the remainder, 18 percent was conducted by firms, and 12 percent each by in-house Federal Government laboratories and FFRDCs.

Federal Obligations for R&D

Federal R&D funding patterns since 1980 clearly reflect government investment priorities. Development grew by 52 percent (in constant dollars), mainly due to defense-related work. (See text table 4-2.) Basic research obligations (see "Definitions," this page) increased 44 percent, exemplifying continued commitment to a strong Federal role in this area. Federally funded applied research has declined 7 percent during the decade. This adheres to stated policy that private industry can—except in national defense and space-related programs—respond to market forces better than the Federal Government in making R&D investment decisions.[6]

Patterns of Federal Agency Support. Federal obligations data collected from agency budgets reveal (1) the relative emphases of the character of work supported by the different agencies, and (2) the specialized relationships that have developed over the years between the agencies and the actual performers of the R&D. The data also show

[5]The growing transfer of funds for R&D from industrial firms to universities and colleges is discussed more fully in chapter 5.

[6]See also Office of Science and Technology Policy (1989).

See appendix table 4-13.

Science & Engineering Indicators—1989

that, over time, Federal support for R&D activities is becoming increasingly concentrated in fewer agencies.

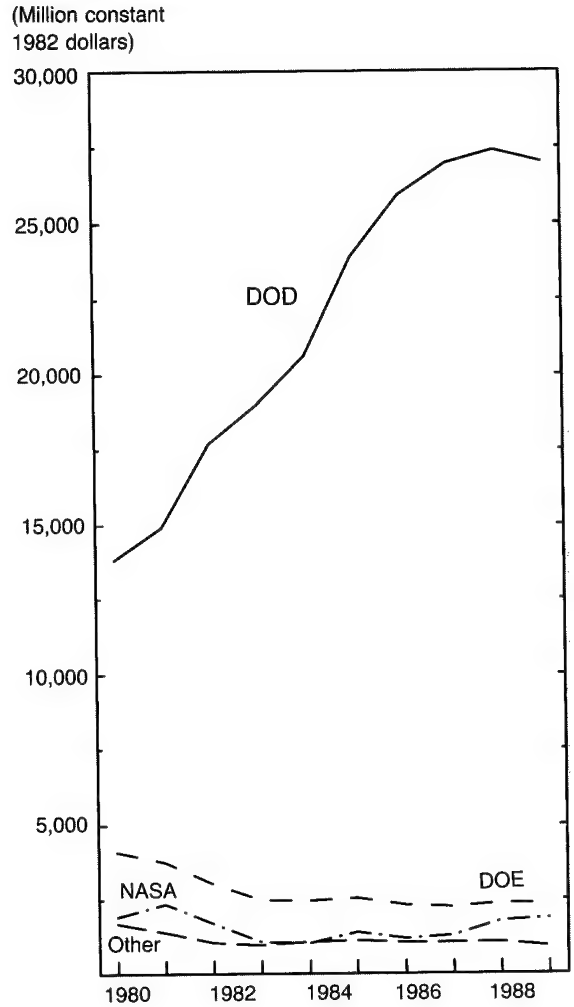
The Department of Defense (DOD) dominated Federal support of developmental work, accounting in 1989 for 84 percent of these Federal obligations. (See figure 4-3.) Obligations of the National Aeronautics and Space Administration (NASA) and the Department of Energy (DOE) provided most of the remainder of this category of Federal support (6 percent and 7 percent, respectively). Development supported by all other agencies (3 percent) has declined absolutely over the decade. (See appendix table 4-6.)

Federal support of applied research is less concentrated across the agencies than is development. (See figure 4-4.) DOD obligated $2.4 billion for applied research in 1989, or 26 percent of the total; the National Institutes of Health (NIH) accounted for 19 percent; DOE, 10 percent; and NASA, 18 percent. Together, these four agencies obligated 67 percent of total Federal obligations for applied research in 1980 and 73 percent in 1989. (See appendix table 4-6.)

NIH accounted for the bulk—38 percent—of total Federal support of basic research in 1989, followed by NSF, 17 percent; NASA, 13 percent; DOE, 12 percent; DOD, 9 percent; and the Department of Agriculture (USDA), 5 percent. (See figure 4-4.) The six agencies accounted for 93 percent of Federal obligations for basic research in 1980 and 95 percent in 1989. (See appendix table 4-6.)

Federal Intramural Laboratories. Overall, Federal agencies perform 24 percent of the R&D indicated by their budgetary obligations.[7] In 1989, these in-house R&D ac-

Figure 4-3.
Federal obligations for development, by agency: 1980-89



See appendix table 4-6. *Science & Engineering Indicators—1989*

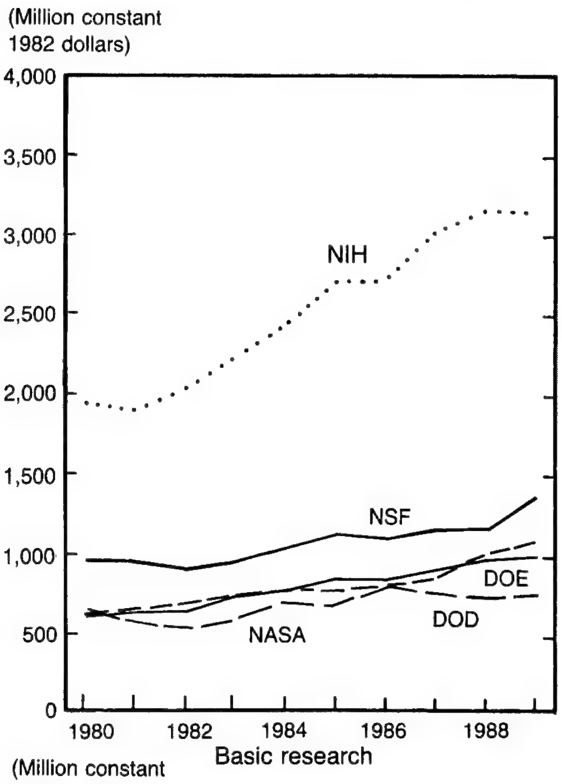
tivities were estimated to cost nearly $15 billion.[8] (See appendix table 4-7.) Obligations to federally run laboratories have increased annually, on the average, by 2.8 percent for basic research and 4.7 percent for development since 1980, though since 1985 this growth has slowed considerably. Between 1988 and 1989, only NASA experienced a positive growth (in constant dollars) in intramural basic research funding. (See appendix table 4-8.)[9]

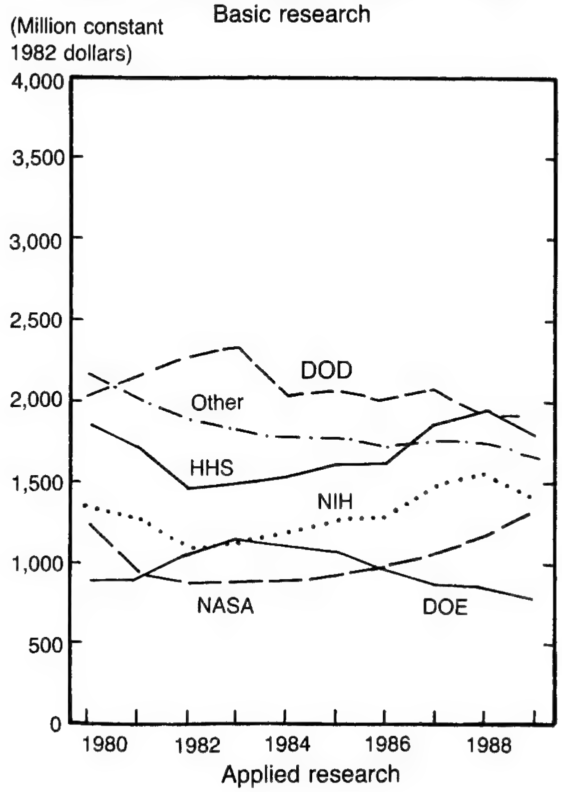
[7]All intramural obligations data include administrative costs of the R&D programs.

[8]Transfers among Federal agencies are included in these data, but are not identified separately here.

[9]Appendix table 4-8 shows an increase for intramural research by the National Science Foundation. However, NSF may not, by law, operate laboratories. NSF intramural funding includes transfers to other agencies, especially to the Department of the Navy for support of NSF Antarctic programs.

Figure 4-4.
Federal obligations for research, by agency: 1980-89





See appendix table 4-6. *Science & Engineering Indicators—1989*

Federal agency expenditures on basic research performed in-house were estimated at $2 billion. NIH supports most of its in-house basic research at its laboratories in Bethesda, Maryland. In 1989, this activity cost about $630 million; this was 16 percent of NIH's basic research budget and 28 percent of the Federal total for intramural basic research. (See appendix table 4-9.) The other two significant funders and performers of intramural basic research are NASA (22 percent of the total in 1989) and USDA (15 percent). The Department of Defense financed 12 percent—or $278 million—of the Federal Government's in-house basic research in 1989, but this was a decrease both in deflated dollars since 1984 ($303 million) and relative to other agency shares. (See appendix table 4-8.)

Federal intramural laboratories in 1989 performed over five times more applied research and development than basic research—$12.5 billion versus $2.3 billion. (See appendix table 4-9.) DOD and NASA, for example, together accounted for 75 percent of total Federal obligations for in-house R&D; and most (69 percent) of this was for applied research and development. Laboratories operated by Federal agencies are overwhelmingly devoted to knowledge discovery or application focusing on the Nation's defense and space policies.

A significant portion (40 percent) of the Federal intramural applied research total is provided by a group of smaller, specialized agencies with important R&D missions. (See appendix table 4-9.) The contributions of these agencies' in-house R&D tends to be obscured by the relatively large R&D intramural obligations of DOD, NIH, and NASA. These smaller agencies and programs include:

- The Agricultural Research Service and Cooperative State Research Service of USDA,
- The Geological Survey of the Department of the Interior,
- The National Oceanographic and Atmospheric Administration of the Department of Commerce, and
- Medical sciences research in the Veterans Administration.

Distinctive R&D Agency-Performer Patterns. Distinctive patterns of support among Federal funding agencies and different types of R&D performers have developed over the years. For example, total Federal R&D obligations to FFRDCs is dominated by funding from DOE and DOD. (See text table 4-3.) Likewise, DOD, NASA, and DOE maintain ongoing specialized relationships for applied research with industrial firms and FFRDCs administered by either universities, industry, or nonprofit institutions. NIH, in contrast, expends the bulk of its applied research and development funds at nonprofit institutes and the research hospitals of the academic sector.

As for basic research, different agencies and different performing sectors play relatively larger roles than in applied research and development. The largest performer of basic research (in terms of total agency basic research obligations) is universities and colleges (52 percent); this sector is primarily funded by NIH (50 percent), NSF (24 percent), and DOD (10 percent). DOE, as in its support of

Science & Engineering Indicators—1989

applied research and development, obligates most—84 percent, or $774 million—of its basic research funds to FFRDCs *under contract with universities.* Federal obligations for basic research in private firms are concentrated in the budgets of NASA and DOD. NASA is especially atypical in its reliance on private firms for basic research, accounting for 59 percent of that sector's total Federal basic research obligations.

Federal funding of basic research in industry has been cyclical over the long term. (See appendix table 4-10.) During the past two decades, total Federal funding of basic research in private firms declined to constant-dollar lows of $206 million in 1975 and $271 million in 1982. The overall trend in the 1980s has been positive, with Federal financing of industrial basic research increasing about 3.5 percent per year in real terms.

These recent increases have not been related to growth in DOD expenditures, however: DOD transfers to industry for basic research have actually decreased annually 3 percent during the 1980-89 decade. Rather, the increases are due to growing support for industrial basic research from NASA (3 percent per year since 1980), NIH (10 percent), DOE (15 percent), NSF (15 percent), and all other agencies (12 percent).

Field of Science and Engineering. Federal obligations for research, distributed across the broad fields of science and engineering, have generally increased in basic research and decreased in applied research over the past 10

years. (See appendix tables 4-11 and 4-12.) In basic research, only obligations for the social sciences have decreased, down about 38 percent since 1980. The environmental sciences have increased at the slowest rates: about 2 percent per year, on the average, since 1980. As a result of these annual incremental changes, the relative shares of Federal obligations to basic research in certain fields have shifted. For example, obligations in the life sciences increased from 44 percent to 47 percent of the total, those in environmental sciences dropped from 11 percent to 9 percent, and the social sciences declined from 3 percent to 1 percent.

Applied research obligated in Federal agency budgets has lost favor during the 1980s; the exceptions to this trend have been mathematics and computer science, which have grown by nearly 9 percent per year. (See appendix table 4-12.)

Federal Defense and Nondefense Obligations

Most R&D obligations of the Federal Government are for defense. In fact, in 1989, an estimated 65 percent of total Federal obligations for R&D were earmarked for this purpose. (See appendix table 4-13.) Between 1980 and 1989, Federal R&D obligations for defense increased by 80 percent. (See text table 4-2 and figure O-5 in Overview.)

Defense-related increases in federally funded R&D have been led by investments in developmental work—mainly for new weapons systems—throughout the 1980s. These investments have nearly doubled in constant dollars. Defense basic research has also experienced real growth—17 percent over the decade—but is less than 1 percent of total defense R&D.

In contrast, nondefense R&D obligations of the Federal Government display a declining pattern over the decade. A 34-percent decrease in development funding (mainly in energy-related technologies), combined with a parallel 7-percent decrease in applied work, resulted in decreased total Federal obligations for nondefense R&D of 3 percent. This decline was not offset by increases in basic research investments of 51 percent.

Independent Research and Development

A unique program of the Federal Government for the support of R&D is *independent research and development (IR&D)*. IR&D consists of in-house and extramural R&D carried out by private contractors on projects they themselves choose in anticipation of the Government's defense and space needs. The Federal Government allows contractors to recover a certain level of their IR&D costs as overhead charges allocated to Federal contracts (both R&D and procurement) on the same basis as general and administrative costs.[10] Only NASA and DOD are significant participants in the program.

[10]Following a DOD technical evaluation of company R&D plans, each major contractor negotiates an advance agreement on the size of its IR&D program. DOD negotiates for all agencies, and the negotiations result in both a ceiling for the contractor's IR&D allowable expenditures and a percentage of these costs that the Government will reimburse. Companies regularly exceed their ceilings, but may not charge these costs to government contracts.

In 1987, industrial firms were estimated to have incurred $4.7 billion in IR&D costs, of which the Government reimbursed $2.2 billion, or 46 percent. (See figure 4-5.) Negotiators for industry have successfully increased this percentage, which was about 39 percent in 1978.[11]

As a proportion of R&D support by DOD and NASA, IR&D has recently decreased. (See appendix table 4-15.) After an increasing trend earlier in this decade, reaching 11.4 percent in 1984, IR&D as a percentage of total support for industrial R&D by the two agencies had fallen to an estimated 8.5 percent in 1987. Moreover, both the absolute IR&D costs incurred by industry and the absolute amounts reimbursed by the Government turned down in 1987 over 1986. NASA's reimbursements decreased sharply in 1986 following the Challenger accident, when many NASA R&D programs were delayed.

[11]The Federal Government has encouraged industry-university cooperation by allowing higher ceilings for IR&D in firms that were able to demonstrate increased interaction with universities using IR&D. See NSB (1985), pp. 43-44.

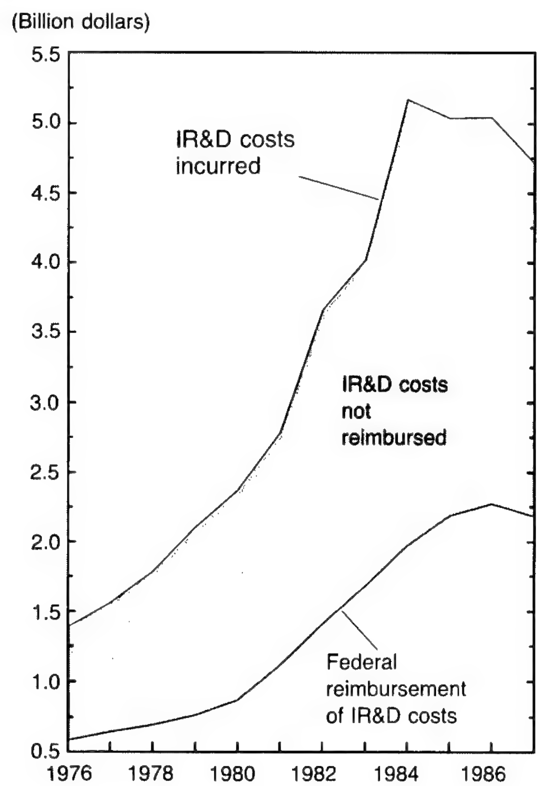
IR&D costs and reimbursements: 1976-87



Note: 1987 data are estimates.
See appendix table 4-14.

Science & Engineering Indicators—1989

Federal R&D Support by National Objective

The Office of Management and Budget identifies 16 budgetary categories, or "functions," that contain Federal R&D programs.[12] These are the functions in which the Federal Government has established national policy objectives as reflected in Federal spending documents.

Five functions are estimated to dominate Federal R&D obligations in 1990, accounting for 93 percent of Federal R&D obligations:

- National defense—65 percent (see "Federal Defense and Nondefense Obligations" discussion, above),
- Health—12 percent,
- Space research—9 percent,
- General science—4 percent, and
- Energy—3 percent. (See figure 4-6.)

Three other functional areas of Federal concern each account for between 1 percent and 2 percent of R&D obligations: transportation, natural resources, and agriculture.

The *nondefense* portion of Federal R&D obligations is dedicated to the functions of health (35 percent), space (26 percent), general science (11 percent), and energy (10 percent). In Federal funds for *basic research* only, health (41 percent) and general science (23 percent) predominate.[13] (See figure 4-6.)

The relative shares of Federal R&D funds devoted to these various functional areas have changed over the decade. Federal funding for energy R&D declined from 12 percent of total obligations in 1980 to 3 percent in 1990. (See appendix table 4-16.) Most of this decrease over the decade reflected Federal policy to leave applied and development work in commercial energy technologies to the private sector.

[12]For definitional details, see NSF (1989b).

[13]By definition, virtually no applied or development work appears in the "general science" budgetary category. In contrast, health and space research each account for about 7 percent of applied and development work combined.

Industrial R&D[14]

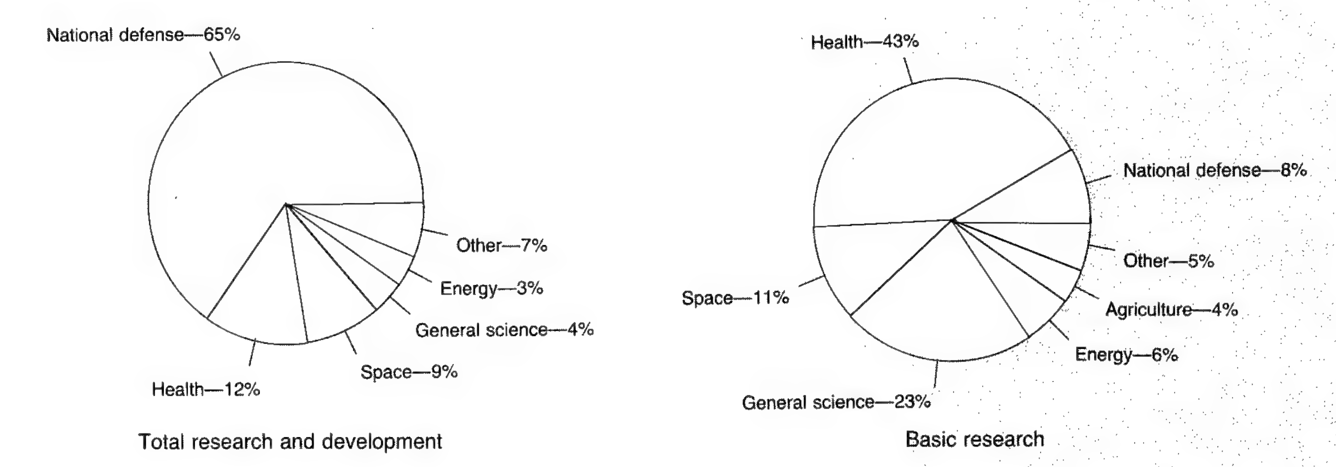
Support for basic research in industry comes largely from companies' own funds; in 1986, 81 percent of basic research expenditures were estimated to have come from companies' own financial resources. (See appendix table 4-18.) The remainder came from the Federal Government. These relative shares have changed little over the past two decades.

Federal funding of industrial basic research is concentrated in two industries. In 1986, about 54 percent of all industrial receipts from the Federal Government for this work were located in the electrical equipment (Standard Industrial Classification—SIC—code 36) and transportation (SIC 37) industries, the latter of which includes aircraft and missiles. (See appendix table 4-18.) Most (52 percent) Federal support of basic research within the electrical equipment industrial group was in communication equipment firms (SIC 366), but firms' own funding dominated this industrial group.

In transportation equipment, however, the pattern was reversed. Federal funding for basic research dominated in both the group overall and in the aircraft and missiles subgroup, providing 55 percent and 65 percent, respectively, of the funding. Overall, 85 percent of all basic research in transportation was located in aircraft and

[14]Industrial R&D is discussed in greater detail in chapter 6.

Figure 4-6.
Federal R&D funds, by budget function: 1990



See appendix tables 4-16 and 4-17.

Science & Engineering Indicators—1989

missiles, underlining the relatively small amount of basic research (i.e., some $46 million) performed in the United States in nonaviation transportation.

Available estimates on large industry groups reflect the R&D funding patterns and missions of the Federal Government. Across all industries, the ratio of basic research to applied research to development was approximately 1:6:24. (See appendix table 4-18.) Ratios among these types of R&D work are different, however, when broken out by source of funds (Federal versus industry funds) and by large industry group. NASA's and DOD's mission funding in the aircraft and missiles group (SIC codes 372 and 376), for example, is reflected in the ratio of Federal Government funding in this industry of 1:10:66; industry's own funding ratio is 1:13:36. In all three categories of R&D work in the aircraft and missiles subgroup, Federal funding accounted for more than 50 percent of the industry's total performance in 1986.

INTERNATIONAL COMPARISONS

R&D Funding as a Percentage of GNP

R&D expenditures as a percentage of GNP has become one of the most widely used indicators of a country's commitment to scientific knowledge growth and development. The industrialized nations of France, West Germany, Japan, the United Kingdom, and the United States have maintained an R&D/GNP ratio of between 2 percent and 3 percent throughout the decade of the 1980s. Differences in emphases among these countries in the types of R&D investments become clear, however, when they are disaggregated.[15]

The funding of R&D as a percentage of GNP has increased in the major industrialized countries over the past 10 years. (See appendix table 4-19.) The approximate 2.6-percent R&D/GNP ratio of the United States has increased by at least half a percentage point (although it decreased in 1984 and 1985). (See figure O-2 in Overview.) The growth in this indicator, however, has not kept pace with the same indicator in Japan and West Germany, both of which now invest a larger percentage—2.9 percent and 2.8 percent, respectively. Both of these countries have now exceeded the U.S. on this indicator for 3 years (1985-87).

Defense and Nondefense R&D Expenditures

Nondefense R&D expenditures as a percentage of GNP in both Japan and West Germany exceeds that of the United States. The Japanese spend a full percentage point more of their GNP on nondefense R&D (see figure O-3 in Overview); West Germany spends eight-tenths of a percentage point more. Furthermore, this ratio has been growing faster during the eighties in other countries than in the United States. Between 1980 and 1987 (the last year for which comparable data are available), countries increased their nondefense R&D/GNP ratio as follows:

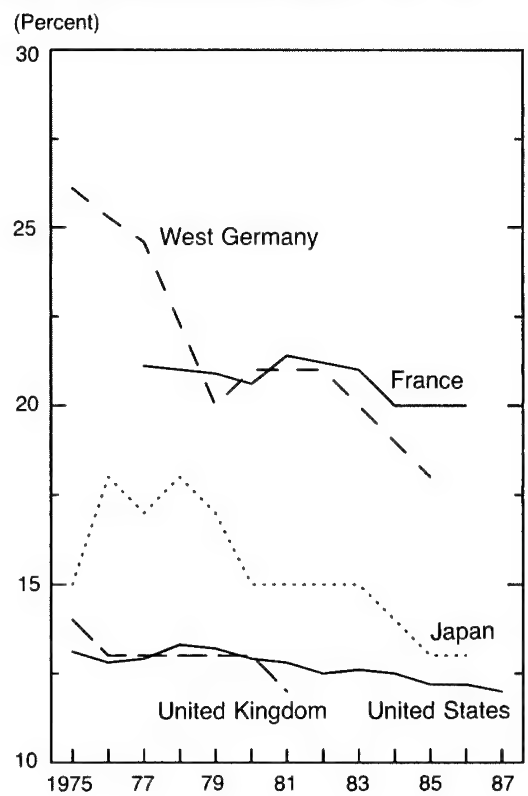
- U.S., from 1.7 percent to 1.8 percent;
- Japan, from 2.2 percent to 2.8 percent;
- West Germany, from 2.3 percent to 2.6 percent; and
- France, from 1.4 to 1.8 percent. (See appendix table 4-20.)

The United States spent approximately $68 billion on nondefense R&D in 1987, compared with $39 billion in Japan and $18 billion in West Germany.[16] The United Kingdom and France invested about $10 billion to $11 billion each. (See appendix table 4-20.) The growth in these investments in Japan has outstripped that in the other industrialized countries. Between 1980 and 1987, for example, Japan's nondefense R&D grew by 69 percent (in constant dollars) compared to U.S. growth of 21 percent. Comparable percentage increases were 43 percent in France and 27 percent in West Germany.

[15]Detailed and more extensive data can be found in NSF (1989c).

[16]See appendix table 4-20 for details on conversion of national currencies to dollars.

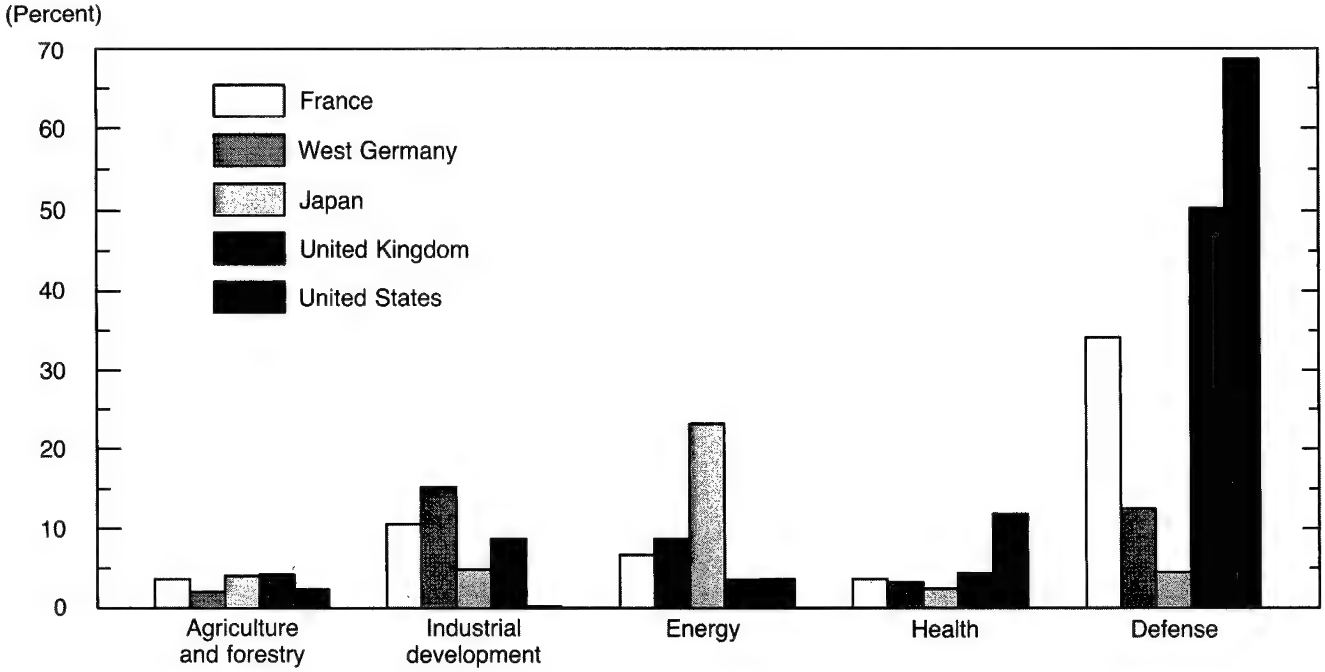
Figure 4-7.
Basic research as a percentage of total R&D



See appendix table 4-21.

Science & Engineering Indicators—1989

Figure 4-8.
Government budget appropriations for R&D, by socioeconomic objective: 1987



See appendix table 4-22.

Science & Engineering Indicators—1989

In 1987, the U.S. invested approximately $11 billion less than Japan, West Germany, the United Kingdom, and France combined in nondefense R&D. On the other hand, in total R&D *including defense*, the U.S. invested $15 billion more than these four nations combined.

Basic Research Versus Total R&D

The United States and Japan devote about the same proportion of their R&D investments to basic research: 12 percent and 13 percent, respectively, in 1986. (See figure 4-7.) France spends about one-fifth of its total R&D on basic research, compared to 18 percent (in 1985) for West Germany.

R&D by Socioeconomic Objective

The relative shares of countries' R&D appropriations reflect striking differences in areas of national interest. In the United States, 69 percent of the total Federal investment in R&D is devoted to national defense, compared to 50 percent in the United Kingdom, 34 percent in France, 13 percent in West Germany, and 5 percent in Japan. (See figure 4-8.) The United States Government also stands out for its investments in health-related R&D (12 percent); this emphasis is especially notable in R&D performed in academic and similar institutions. (See "Fields of Academic R&D" discussion, next page, and appendix table 4-22.) About 4 percent of Government appropriations for R&D in the U.S. are connected with national objectives related to energy and the general advancement of knowledge.[17]

Japanese Government appropriations for R&D are invested relatively heavily in general university research (about 50 percent for "advancement of knowledge" and "general university funds"—GUF—combined). The Japanese also spend about 23 percent of their governmental R&D funds on energy-related R&D, reflecting the country's concern with its heavy dependence on foreign sources of energy.

The Government of West Germany invests heavily in R&D related to industrial development—15 percent of its total 1987 investment versus 11 percent in France, 5 percent in Japan, and 0.2 percent in the United States. The small proportion of U.S. investments in industrial development reflects a long-standing policy of the U.S. Government to rely on private sector investment decisions in this area.

[17]In the U.S., "advancement of knowledge" is a catch-all budgetary category for basic research unrelated to a specific national objective. "General university funds," which contain some basic research funds, cannot be separately distinguished in the United States. See, however, the "Fields of Academic R&D" discussion, next page, and Martin, Irvine, and Isard (forthcoming).

Fields of Academic R&D

Differences in R&D-performing institutions, and different institutional accounting practices, confound efforts to compare different countries' R&D investments and emphases. This is particularly true in the case of academic R&D, which comprises hundreds of different accounting systems.

A recent analysis performed at the Science Policy Research Unit (SPRU) in Sussex, England, and jointly sponsored by NSF and Britain's Advisory Board for the Research Councils permits international comparisons—by field—of academic and academically related research (Martin, Irvine, and Isard, forthcoming). These research activities are closely tied to the growth of disciplinary public knowledge commonly published in the scientific literature. Because it plays such an important role in social and economic progress, the growth of such knowledge is widely viewed as critical in national R&D investment strategies.

In the United States, a particularly thorny problem in collecting data on academic R&D concerns general university funds (GUF). U.S. universities have been increasing their own funding of R&D, but what proportion of these GUF funds support R&D? The data describing university support for R&D elsewhere in this chapter do not include GUF that support R&D *and* are not identified by the universities as support for specific research projects. (See appendix tables 4-2 and 4-5.) This issue arises particularly in the case of public universities, which receive general appropriations from state governments and then distribute them among different activities, including some research activities.

The SPRU analysts produced an estimate of support for academic research otherwise subsumed in GUF as follows. Using the percentage of work time that faculty spend on research, they calculated a "faculty-salary" contribution in GUF. This GUF contribution to academic research support involved multiplying the number of faculty in public universities by a coefficient derived from the percentage of time academic faculty spend on research, and multiplying the resulting "research full-time equivalent personnel" by average 9-month salaries, including fringe benefits. To generate broad field estimates, the analysts then distributed their total estimate across fields according to the distribution of academic staff in the different fields. Thus, in the SPRU analysis, academic R&D financed by university funds consists of the GUF faculty-salary contribution, plus other institutional funds set aside specifically for research.

The U.S. academic and academically related R&D support in figure 4-9 and appendix table 4-23 thus consists of three parts. (Details of the equivalent numbers for other countries can be found in Martin, Irvine, and Isard, forthcoming.)

1. *University support for research:*
   - Institutions' own funds set aside specifically for research, and
   - The GUF contribution discussed above.
2. *Separately budgeted academic research:*
   - Federal, state, and local current and capital R&D expenditures on campuses;
   - Federally financed fellowships; and
   - An estimate of project management costs borne by the Federal funding agency.
3. *Academically related research:*
   - Activities of the 19 FFRDCs administered by universities (in 1987) that relate to provision of central facilities for academic researchers, and
   - Intramural research of the NIH. For other countries in the analysis, this last category includes research council establishments of the type common in European countries, as well as various agricultural and medical institutes, especially those with a role in postgraduate training. Examples include the Max-Planck Institutes in West Germany and laboratories of France's *Centre National de la Recherche Scientifique* (CNRS).

STATE-LEVEL SUPPORT FOR SCIENCE AND TECHNOLOGY[18]

Indicators of recent increased state-level support for science and technology are of two types:

- New organizations in state governments established specifically for the development of science and technology, and
- Increased state funding for S&T-related activities, including R&D.

The following sections present data and analysis from a recent survey of the state S&T agencies in 13 states, and state R&D expenditure data from a special national survey.

History

In recent years, much publicity has accompanied the creation of new state S&T programs designed to enhance the states' technological and competitive capacities. The history of state programs supporting S&T can be divided into three periods characterized by particular underlying economic, sociological, and political forces.

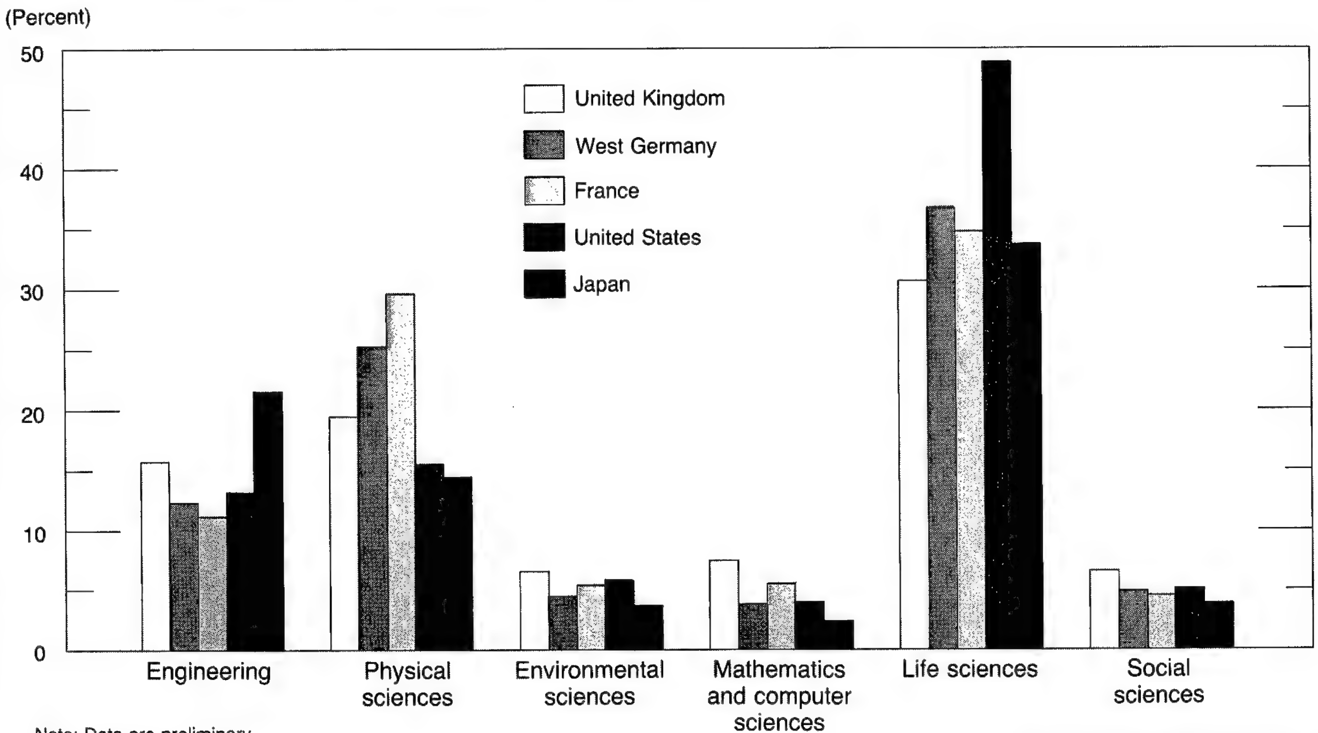
From the Morrill Act to 1980. The *first phase* in the relationship between states and S&T began when President

[18]"S&T" is used in this section to emphasize the broad range of state activities in the support of economic development based on science and technology.

The SPRU analysis shows that all of the countries emphasize the life sciences in their academic research, with the U.S. devoting almost half its academic support in this broad field. (See figure 4-9.) The U.S. also stands out in its investment of larger absolute amounts of financial resources across all broad S/E fields. (See appendix table 4-23.)

France emphasizes the physical sciences, investing 30 percent of its total academic R&D. Other European countries also invest more in the physical sciences relative to the United States and Japan. The Japanese stand out in their relatively strong support of academic R&D in engineering, though the U.S. spends absolutely more than twice as much as Japan in this category.

Figure 4-9.
Academic and academically related research, by field and country: 1987



Note: Data are preliminary.
See appendix table 4-23.

Science & Engineering Indicators—1989

Lincoln signed legislation establishing the U.S. Department of Agriculture. In 1862, the Morrill Act granted the states Federal land for the establishment of what later became known as the "land grant" colleges and universities. Since then, virtually all states have been active in the support of new knowledge development in agriculture and the dissemination of this knowledge to agricultural users. The Federal Government contributed to this institutionalization through:

- USDA's Agricultural Research Service, with its network of research facilities throughout the Nation;
- The Cooperative State Research Service; and
- The Agricultural Extension Services.

With the expansion of the land grant universities, a model evolved for cooperation of the Federal, state, university, and industry sectors in the support of S&T-based economic development.

A *second phase* for state S&T interests was initiated shortly after World War II, when existing programs were eclipsed by the rapid growth of Federal S&T programs and agencies. Federal support of science and technology—especially for defense, space, and health-related objectives—had considerable impact on states and regions. Federal funds for research and the education of veterans contributed to the very rapid growth of institutions of higher education, and some schools began to emerge as significant national research institutions. Regional institutions, including technical institutes and most land grant schools, expanded

their engineering programs. They also frequently developed special relationships with local industries. Organized research units proliferated on campuses, separated from traditional disciplinary departments.[19] These new research units usually had a more applied orientation than the academic departments.

Industries—particularly those performing defense and space work—were attracted to the supply of talent at universities or at specialized government installations (e.g., California, Texas, and Florida for space programs; California, Massachusetts, and Washington for defense programs). By locating businesses in these areas, concentrations of regional development emerged. At least one state, North Carolina (which established its Board of Science and Technology in 1963), explicitly intended to recreate the conditions underlying other regional development patterns by capitalizing on a network of public and private universities around Chapel Hill in what has become known as the "Research Triangle." Thus, a state's strong tradition of public support for education was channeled into an outright effort to bring together in one region the academic expertise of several universities for the purpose of high-tech development.

Concurrently, a brief flurry of state activities in support of S&T occurred in the 1960s. Under the State Technical Services Program of the U.S. Department of Commerce, some states created S&T commissions and foundations, and some appointed science advisors to the governor. In the 1970s, NSF, through its Intergovernmental Science and Technology Program, supported the formation of organizations to provide S&T information to state governments. It also helped to establish state S&T advisors and boards, which were often located in legislative branches. Although a few of these offices survive, they are separate from the new, action-oriented institutions discussed below, most of which are executive branch agencies and some of which are in the governor's office itself.

The 1980s. A *third phase* in state support for S&T started in the early 1980s.[20] States began establishing agencies to promote S&T development, and by 1988 at least 38 states had such offices.[21]

Several factors underlie this growth of state-level institutions for S&T. First, economic dislocations in some states forced them to search for models for economic growth based on S&T. For example, some states in the Midwest and Northeast faced declines in their traditional "smokestack" industries and turned their attention to an existing resource—research universities—as the centerpiece of new economic development policies. This practice was aimed at:

- Creating and attracting knowledge-intensive industries to replace those declining because of new technologies, reduced markets, or foreign competition; and
- Encouraging modernization by existing but troubled manufacturing industries.

Similarly, oil-producing states like Texas, Oklahoma, and Alaska—which experienced severe economic declines when oil prices dropped—also enacted S&T-promoting agencies and programs. These initiatives were usually undertaken in the executive branch, and often figured prominently in gubernatorial contests. In fact, the National Governors' Association itself has played a significant role in promoting the awareness of the S&T role in economic development.[22]

Second, the new state initiatives reflected changes in the Federal approach to science investments. Some new Federal programs began to require state and/or industrial matching funds. States were also keenly aware of the size of some large new scientific and technological enterprises—e.g., DOD's Sematech (a consortium to develop manufacturing technologies) and the Microelectronics and Computer Technology Corporation (MCC), both now located in Texas—and the need for coordinated efforts involving state, industrial, and university resources in competing for such initiatives. Announcement by the Federal Government of the Superconducting Super Collider (SSC) project also galvanized the interest of many states.

Third, changes in the nature of S/E research required not only the construction of very large scientific instruments but also new institutional forms for cross-disciplinary work. And these changes inevitably brought greater political attention to how these awards were made. In efforts to build capabilities for S&T in specific institutions—and as a result of intense lobbying by universities themselves—the U.S. Congress began inserting specific line items for research facilities in appropriations bills.[23]

New Institutional Developments

State agencies for S&T-based economic development, although they vary greatly in scope, budget, and influence, share one common characteristic: their objective is the support of S&T for economic development, and not the support of research for its own sake.

Among the 13 state S&T agencies studied,[24] agency funding varied from a low of $78,000 in Texas (FY 1988) to a high of $36 million in Pennsylvania (FY 1987). (See appendix table 4-24.) In addition to state budgetary obligations, most state agencies operate programs that require matching funds from the participating institution or business.

Level of funding, however, depends upon whether the agencies operate programs or are only advisory. State agencies with programmatic responsibilities tend to have larger budgets. Of the 13 studied, 2 state agencies have

[19]NSB (1985), pp. 109 and 282.

[20]This and the following sections rely heavily on Lambright, Price, and Teich (forthcoming). The study focused on "showcase" state agencies in 13 states responsible for promotion of S&T, and not on all agencies within a state with S&T-related missions.

[21]National Governors' Association (1988).

[22]See National Governors' Association and the Conference Board (1987). For a discussion of the political reasons for establishing these programs, see Feller (1984).

[23]See Savage (1989).

[24]Lambright, Price, and Teich (forthcoming).

only advisory roles (Texas's Office of Advanced Technology and North Carolina's Board of S&T), and their budgets are relatively low.[25]

Four of the thirteen states use the agency director as the science advisor to the governor, though this function can be unofficial (as in Arkansas) or can change from one governor to the next (as in Florida). All agencies receive advice and direction from boards of directors; in this way, board members from the business and academic communities are expected to bring their particular interests to bear on agency programs.

Some states have targeted their agency programs to have regional effects. Massachusetts, for example, has sponsored centers for R&D at regional universities and institutes of technology away from Boston; Pennsylvania established four regional offices to operate its Ben Franklin Partnership; and New York has distributed its Centers for Advanced Technology around the state.

State S&T agencies are in different stages of development. For example, although both Alaska and California established their state offices for S&T development in 1988, Alaska has embarked on a program of "capacity building" for its state S&T; California, on the other hand, is a highly developed state in terms of science and technology.[26]

While most of these agencies are relatively new, roles in the older ones have evolved. The New York S&T Foundation, for example, founded in 1963, has evolved into an important agency with a staff of 26 and sponsoring $14 million in R&D support out of a budget total of $24 million in 1987. (See appendix tables 4-24 and 4-25.) North Carolina's Board originally sponsored research centers and then spun them off to other agencies, but recently has ended its grants program.

The agencies also support S&T activities other than R&D. Six of the thirteen provided funds for purchase of scientific equipment or construction of facilities, and nine sponsored technology transfer programs. (See appendix table 4-25.) One of the more novel forms these non-R&D programs may take is the provision of venture or "seed" capital for company start-ups, sometimes using state pension funds: 7 of the 13 states provided some kind of business start-up support. Other more strictly business-oriented programs include support for incubators, assistance in qualifying for Small Business Innovation Research programs of the Federal Government, managerial and technical assistance, and establishment of research parks. Some states also have special tax incentives for S&T-related business development.

[25]Both Texas and North Carolina also have other agencies with operating funds. Texas only recently established a separate grants program after long years of opposition to such a centralized bureau. See Texas Higher Education Coordinating Board (1988).

[26]See Alaska Science and Technology Foundation (1989). Lambright, Price, and Teich (forthcoming) report that the California office was established at least partly in response to the state's having lost out on several national awards and competitions, including the NSF-sponsored Earthquake Research Center, DOD's Sematech, and DOE's Superconducting Super Collider.

Funds for R&D by State

Two sources of data on state support of R&D (as opposed to broader *S&T* activities) are available for the 50 states, i.e.:

- An annual survey of expenditures for R&D by academic institutions, and
- A survey of state agency R&D expenditures.

Although they overlap to an unknown extent and use different methodologies, both of these indicators show growth in state support of R&D. Data on support for academic R&D also show increasing support by industry for R&D performed on the Nation's campuses, one of the goals of states' S&T policies.[27]

Academic R&D. In the annual survey of expenditures for R&D by academic institutions, university offices of research administration report the source and amount of support for separately budgeted R&D performed on their

[27]See also chapter 5, pp. 110-111.

Text table 4-4. Change in academic R&D funded by industry, by state: 1978-87

Rank/state	Academic R&D funded by industry 1978	1987	Change in state total percentage 1978-87
	(Percent)		
	(a)	(b)	(b - a)
1 New Mexico	6.4	15.8	9.4
2 Idaho	3.5	11.7	8.2
3 Vermont	1.1	9.1	8.1
4 Missouri	1.8	9.2	7.4
5 Rhode Island	1.7	8.2	6.5
6 Washington	3.5	9.0	5.5
7 Alabama	1.8	7.1	5.4
8 Maine	6.8	12.1	5.3
9 Georgia	5.3	10.4	5.0
10 Arkansas	3.0	8.0	5.0
11 Nevada	9.8	14.5	4.7
12 Florida	3.6	8.2	4.7
13 Montana	6.0	10.6	4.6
14 Mississippi	2.7	7.2	4.6
15 Massachusetts	4.1	8.3	4.2
16 Pennsylvania	5.9	10.1	4.2
17 California	0.8	4.7	3.9
18 Indiana	5.3	9.1	3.8
19 Texas	2.7	5.7	3.0
20 Tennessee	6.6	9.6	3.0
21 North Carolina	4.6	7.6	3.0
22 Kansas	2.9	5.8	2.9
Average of all states	3.7	6.4	2.7

See appendix table 4-26.

Science & Engineering Indicators—1989

campuses. Doctorate-granting institutions reported about $1 billion of support for R&D from state and local sources in 1987. (See appendix table 4-27.)

These same data broken out by state reflect differing state resource patterns and show the effects of different institutional mixes in individual states. Eleven states account for over 50 percent of total national academic R&D expenditures from state and local sources.[28] (See appendix table 4-27.) These sources in Texas, with a strong tradition of direct funding of institutional activities, account for 11 percent of the state's total academic R&D and 9 percent of the national total of these funds. In contrast, in California—whose total academic R&D expenditure is nearly twice that of Texas—state and local sources accounted for only 2.4 percent of the state's academic R&D performed in 1987, reflecting the large Federal funding and the presence of large private research universities in that state which were less likely to receive state funding for R&D. Pennsylvania also ranks relatively low on this measure.

Insofar as state S&T policy objectives include encouragement of university-industry interactions, industry support of university R&D may serve as one indicator of the success of those policies.[29] For all states combined, industrial sources of support for academic R&D have grown faster than all other sources of support, increasing 179 percent in constant dollars from 1978 to 1987. (See appendix table 4-27.) As a percentage of total R&D support on all of the Nation's doctorate-granting campuses, industry sources of support increased from 4 percent to over 6 percent. (See text table 4-4.) Some states experienced notably larger increases in the proportion of their academic R&D from industrial sources. Many of these are states that rank low on total academic R&D expenditures, though greater than average increases have also occurred in several of the largest academic R&D-performing states, including Pennsylvania, Massachusetts, and Washington.[30]

State Agency R&D Expenditures. NSF recently resurveyed state agency R&D expenditures. (See appendix table 4-27.) To ensure comparability with a similar survey conducted in 1977, the survey of 1987 and 1988 expenditures excluded academic R&D expenditures. (However, some portion of the reported state agency expenditures may be assumed to have gone to academic institutions.)

Like the data reported above, total state agency expenditures for R&D from state sources of funds have increased overall, doubling between 1977 and 1988 to about $600 million (in constant dollars). States varied widely on this indicator, with some states reporting declines in real dollars. As noted earlier in this section, a state's political culture and history influence its reliance on state agencies to disburse R&D funds: some states appropriate most funds directly to institutions themselves, and this source of support for R&D is not reflected in these data.

[28]These data show only state and local government sources of funds that are separately budgeted for specific projects. General university funds (GUF) used for academic R&D purposes are not included here.

[29]See "Industrial Support of R&D at Specific Academic Institutions" discussion in chapter 5.

[30]Within states, however, individual institutions often account for much of the movement of these indicators.

Chapter 5
Academic Research and Development: Support, Personnel, Outputs

CONTENTS

Academic Research and Development: Support, Personnel, Outputs

HIGHLIGHTS

Funding for Academic R&D

- *The 1980s have been a decade of rapid growth in U.S. academic research and development (R&D).* From 1980 to 1989, real growth (in constant 1982 dollars) in academic R&D expenditures averaged 4.9 percent annually; the estimated 1988-89 growth rate is 3.0 percent. Funding increased in current dollars from $6 billion in 1980 to an estimated $14 billion in 1989, reaching 10.5 percent of estimated total U.S. R&D expenditures in 1989. (See pp. 107-108.)
- *The Federal share of academic R&D support has decreased,* while the non-Federal share of academic R&D funding reached an estimated 41 percent in 1989. (See p. 108.)
- *Industry's share of academic R&D funding grew from 3.9 percent in 1980 to an estimated 6.6 percent in 1989.* While most of these funds go to the better known research universities, a number of smaller, more specialized, institutions received over 20 percent of their total R&D funding from industry in 1987. (See p. 110.)

Facilities and Instruments

- *U.S. research universities saw large increases in capital investments in science and engineering (S/E) facilities during the 1980s, with expenditures reaching $1.8 billion in 1987.* Capital expenditures for S/E plant and equipment grew 7 percent annually in constant dollars between 1980 and 1987, compared with an average annual *decrease* of 9 percent between 1970 and 1980. Growth was largely due to increased support from non-Federal sources. Numbers of instruments available for academic R&D also increased during the 1980s. (See pp. 111-113.)

Characteristics of Doctoral Researchers in Academic R&D

- *The number of doctoral scientists and engineers whose primary or secondary work activity was academic R&D reached 155,000 in 1987—a 65-percent increase over the number in 1977.* Twelve percent of the total were engineers, the same proportion as in 1977. The greatest growth rate was seen for computer/information specialists, whose numbers tripled to 3,500. Approximately one-third of the doctoral scientists and engineers are life scientists; this is the largest single group. (See p. 115.)
- *Women and minorities increased their percentages in the academic doctoral R&D workforce between 1977 and 1987, but whites still made up almost 90 percent of that workforce and white males 75 percent in 1987.* Asians were 9 percent of the S/E doctoral workforce, and other minorities less than 2 percent. The proportion of women doctorates in academic R&D increased from 10 percent to 16 percent during the decade. (See pp. 115-116.)
- *Researchers in academic institutions or industry tend to continue working in the same employment sector to a greater extent than researchers in the Federal Government or nonprofit organizations, over periods of 2 to 14 years.* Related data indicate that the largest turnover of S/E doctoral researchers into other work activities occurs during their first few years in research. (See pp. 118-119.)

S/E Publication Data

- *In 1986, U.S. authors produced 36 percent of the world scientific literature, a proportion that has remained relatively stable since 1973 in the data base used for these analyses.* The USSR, United Kingdom, and Japan were next in overall proportions of world scientific publications with 8 percent each. U.S. academic institutions produced 70 percent of the U.S. S/E literature in 1986, and about 25 percent of the world S/E literature. (See p. 120.)
- *Multi-authored papers are on the rise, suggesting that individual researchers are increasing their interactions.* More than 30 percent of papers in 1986 had four or more authors, up from 15 percent in 1973. (See p. 120.)
- *U.S. researchers are increasing their publication of S/E articles with foreign authors.* In 1986, 10.2 percent of publications with at least one U.S. author were internationally coauthored, up from 5.6 percent in 1981. (See pp. 120-121.)
- *S/E researchers from industry are increasingly coauthoring papers with U.S. university researchers, suggesting a rise in cooperation between these two sectors.* Of articles with at least one industry author, 28 percent were coauthored with a university author in 1986; this was almost double the 1976 figure. (See p. 121.)
- *Citation patterns indicate that U.S. papers on average exert more influence on foreign researchers than foreign papers exert on U.S. researchers.* (See pp. 122-123.)

Patents and Products

- *Academic institutions are patenting more frequently.* The number of university patents increased from an annual average of 492 in the early 1980s to 801 in 1988. Universities received 2.0 percent of patents awarded to U.S. inventors in 1988, more than double the 0.9-percent university share in 1978. Four biomedical patent classes accounted for one-third of all patents awarded to universities in 1988. (See pp. 123-124.)

R&D expenditures, an estimated 68 percent went for basic research, 25 percent for applied research, and 6.3 percent for development.

In constant 1982 dollars, academic R&D increased an estimated 54 percent between 1980 and 1989. R&D growth during the 1985-89 period is expected to be stronger for the academic sector than for any other economic sector. However, the annual rate of growth for academic R&D in 1988-89 is estimated at 3.0 percent, down from an estimated 4.9 percent during 1980-89.[5]

Support by Sector

The Federal Government provides the majority of funds for academic R&D, but other sources have been contributing increasing proportions in recent years.[6] (See figure O-20 in Overview and appendix table 5-2.) In 1989, the Federal Government provided an estimated 59 percent of the funding for R&D performed in academic institutions; this was down considerably from 72 percent in 1969. Academic institutions that perform the R&D provide the second largest share. Over the 1969-89 period, the institutional share has grown from 10 percent to an estimated 18 percent.[7] Industry increased its share to an estimated 6.6 percent in 1989, while state and local governments supported about 8 percent of academic R&D throughout the 1980s.

Private and public universities differ in their major sources of R&D support. For public academic institutions, 34 percent of R&D funding in 1987 came from state and local funds and institutional funds; private academic institutions received only 11 percent of their funding from these sources. (See appendix table 5-3.) Between 1980 and 1987, the Federal share of support decreased for both public and private institutions, dropping from 61 percent to 53 percent (public institutions) and from 79 percent to 74 percent (private institutions).

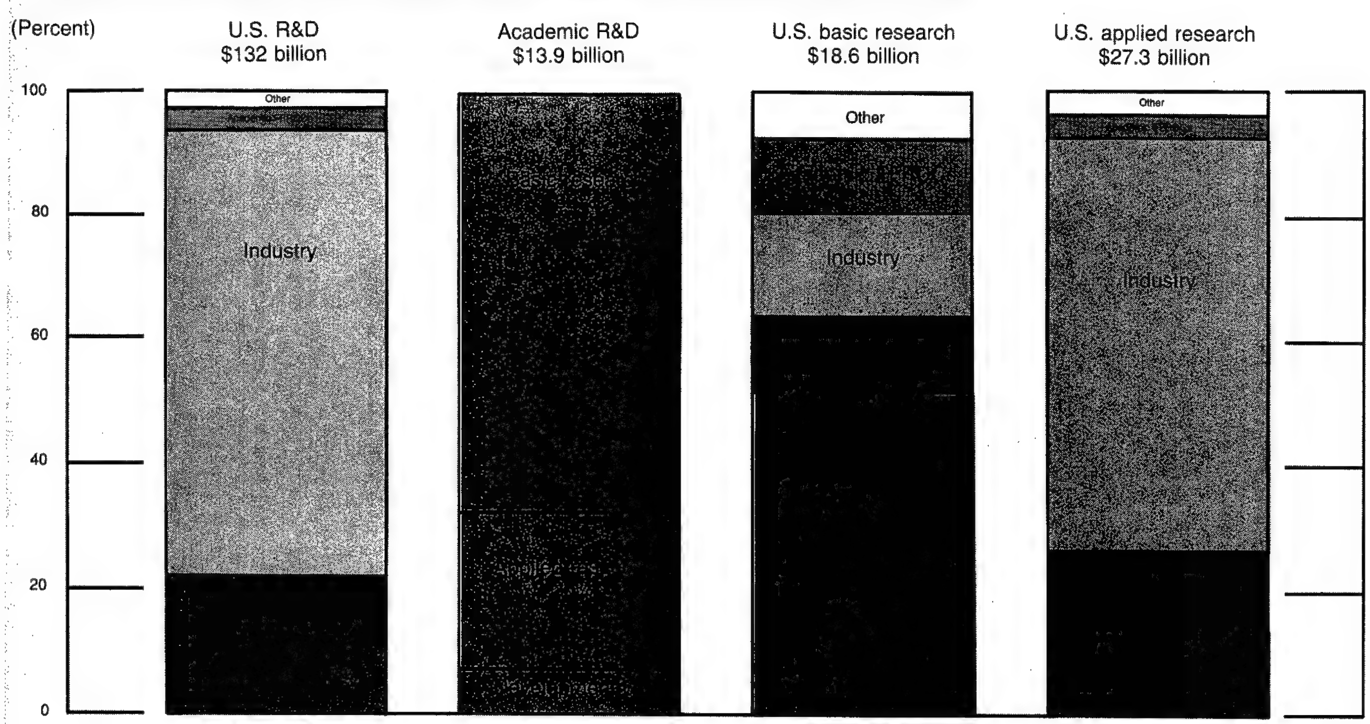
---

[5]NSF (1989b).

[6]Academic R&D is essentially funded via grants, contracts, and cooperative agreements. Funding usually includes expenditures for nonfixed equipment.

[7]Institutional funds are those an institution spends on R&D, including unreimbursed indirect costs associated with R&D projects financed by outside organizations and mandatory cost sharing on Federal and other grants. Sources of these funds are (1) general-purpose state or local government appropriations; (2) general-purpose grants from industry, foundations, or other outside sources; (3) tuition and fees; and (4) endowment income. See NSF (1989c).

Figure 5-1.
Academic and national R&D expenditures by character of work and performer: 1989



Note: Data are estimates.
See appendix table 5-1 and chapter 4.

Science & Engineering Indicators—1989

- *Manufacturing industries depend substantially on academic research for development of new processes and products.* The first empirical attempt to estimate the economic return to society from academic research found an annual social rate of return of 28 percent for the seven industries studied. (See p. 124.)

Academic research and development (R&D) is a major part of the U.S. science and engineering (S/E) structure. It accounts for an estimated 10.5 percent of total R&D expenditures in the Nation and about half of U.S. basic research expenditures. There were 155,000 doctoral scientists and engineers in academic R&D in 1987, comprising 37 percent of the doctoral S/E workforce. Researchers in U.S. academic settings publish 70 percent of the S/E articles that U.S. researchers publish and 25 percent of the world S/E literature.

A major theme in this chapter is that academic R&D is becoming increasingly interactive. Of particular interest—given the current concern with accelerating the commercialization of university research findings—are the growing numbers and types of interactions with industry. Growth in industrial funding of academic R&D and in numbers of industry-university coauthored publications provides evidence of increased contacts.

This chapter addresses three major aspects of academic R&D:

- *Support*: sources of funding and its allocation among recipients and disciplines,
- *Personnel*: characteristics of academic doctoral researchers, and
- *Outputs*: publications, patents, and commercial use of academic research findings.

In some analyses, for example, those involving S/E publication patterns, the discussion extends beyond the U.S. academic sector to encompass other sectors and other countries.

The chapter opens with a discussion of trends in funding and support for academic R&D, particularly changes in the sources of support. The Federal Government is the major supporter of academic R&D, but a large amount of funding comes from other sources. Recent increases in funding for both facilities and instrumentation have improved these aspects of the academic R&D infrastructure, although large backlogs remain. New this year is a discussion of some of the problems faced by research libraries as already expensive S/E periodicals continue to increase in price.

Discussion about the academic R&D workforce is limited to scientists and engineers with doctoral degrees, since they are the major actors in academic science and engineering research.[1] Trends in the growth of various disciplines and in the numbers of women and minorities in academic R&D fields are addressed. The chapter includes some comparative data about doctoral scientists and engineers in nonacademic basic research. Also, for the first time in the *Science & Engineering Indicators* series, data are presented about retention rates for doctoral researchers in specific employment sectors and in research activities over time periods as long as 14 years.

As the major research output of academic R&D, publications receive detailed attention. Coauthorship data show increasing cooperation in research activities among individuals, employment sectors, and countries. Citation patterns provide information about the amount of attention that researchers from particular sectors and countries give to other researchers. As part of a new analysis of citations, the chapter includes citation data for some individual countries.

Data on another output of academic R&D—patents—show that university patenting is increasing, a finding consistent with the increasing cooperation between universities and industry. On a related topic, a recent study shows that academic R&D has contributed substantially to new commercial products and processes in some industries.

ACADEMIC RESEARCH AND DEVELOPMENT: SUPPORT[2]

In 1989, the U.S. spent an estimated $13.9 billion for R&D at academic institutions.[3] (See figure 5-1 and appendix table 5-1.) This expenditure continues a gradual 20-year trend, as rising proportions of total national R&D expenditures are allocated to academic R&D: in 1969, 8.7 percent of such expenditures went to academic R&D, compared with an estimated 10.5 percent in 1989.[4] Of 1989 academic

[1]Chapter 3 discusses the overall S/E workforce.

[2]Data in this chapter come from several different National Science Foundation (NSF) surveys that do not always use comparable definitions or survey methodologies. For example, the survey on which the publication *Federal Support to Universities and Colleges and Selected Nonprofit Institutions* (NSF, 1988c) is based obtains information on Federal "obligations" to universities and colleges directly from Federal funding agencies. By contrast, the survey on which *Academic Science/Engineering: R&D Funds* is based (NSF, 1989c) obtains data directly from the universities and colleges on their R&D "expenditures." The results do not exactly match with Federal obligations.

For descriptions of the methodologies of these and selected other National Science Foundation surveys, see NSF (1987b).

[3]In this section, academic institutions generally comprise institutions of higher education that grant doctorates in science or engineering and/or spend at least $50,000 for separately budgeted R&D (NSF, 1989c). Federally funded research and development centers associated with universities are tallied separately; these are discussed in chapter 4.

[4]Chapter 4 discusses patterns of national R&D expenditures.

Federal Support for Academic R&D

Federal Support for Academic S/E Activities. Before discussing Federal patterns of academic R&D funding, it is useful to understand where academic R&D fits in the overall scheme of Federal support for academic S/E activities.[8] Federal funds provide support for the following academic S/E programs:

- R&D plant (facilities and equipment);[9]
- Facilities and equipment for instruction;
- Graduate student fellowships, traineeships, and training grants;
- General support for S/E research and education, without precise specification; and
- Other S/E activities, such as technical conferences, undergraduate activities, and teacher institutes.

Approximately 15 Federal agencies provided over 95 percent of S/E funds obligated to academic institutions for these various purposes in 1987.

In 1987, about 85 percent of Federal obligations for academic S/E were for R&D, in contrast to 66 percent in 1971. (See appendix table 5-4.) Fellowships, R&D plant, and general S/E activities each accounted for about 3 percent of total Federal academic S/E obligations in 1987; "other" activities accounted for about 6 percent. (See figure 5-2.)

Changes over time in the amounts of Federal support for various types of S/E programs may reflect shifts in policy and priorities. R&D was the only area of academic S/E where Federal funding increased (in constant 1982 dollars) during the 1970s.[10] However, support programs for women and minorities continued during the 1970s, and various types of support were devoted to such rapidly developing disciplines as computer science, materials research, and biotechnology. In contrast, a period of strong Federal support for graduate training ended around 1970. Between 1971 and 1980, Federal support for graduate research fellowships and traineeships declined by 75 percent, and, unlike support for other Federal S/E programs, did not recover during the 1980s.[11]

The Reagan Administration formulated a positive policy towards academic S/E support in 1983, as reflected in the subsequent S/E funding pattern. Large recent increases in Federal funding for facilities (over 100-percent increase in 1987 compared with 1986) partially reflect special line-item budgetary appropriations inserted by Congress for specific academic institutions.[12]

Support of Academic R&D by Federal Agencies. Federal obligations for academic R&D are increasingly concentrated in three agencies: the National Institutes of Health (NIH), NSF, and the Department of Defense (DOD). Together, these agencies provided an estimated 80 percent of total Federal financing of academic R&D in 1989, up from 66 percent in 1969. (See appendix table 5-5.) NIH, NSF, and DOD, as well as the National Aeronautics and Space Administration (NASA), are each estimated to have experienced between 3-percent and 5-percent average annual growth (constant 1982 dollars) in their funding of academic R&D during the 1980s. NIH was estimated to have provided almost 50 percent of all Federal support for academic R&D in 1989; the NSF share was estimated at 17 percent. DOD, after increasing its share of Federal support from 9 percent in 1977 to 16 percent in 1986, declined to an estimated 14-percent share in 1989.

University-Administered Federally Funded Research and Development Centers. During World War II and in the postwar period, several Federal agencies with

[8]Data on types of Federal funding for S/E activities come from a survey of the 15 Federal agencies most heavily involved in S/E support to academic institutions. See NSF (1988c) for the methodology used in the survey. Findings regarding Federal funding for other R&D-performing institutions, such as private foundations, exhibitors, and trade associations, also can be found in NSF (1988c).

[9]Federal support of S/E facilities and equipment for R&D and instruction are discussed under "Academic R&D Facilities and Instrumentation"; see pp. 111-13.

[10]For a detailed history of R&D during the Reagan Administration, see Teich and Gramp (1988).

[11]A concomitant rise in graduate research assistantships, included in these data under "R&D," has partly filled this gap. See chapter 2.

[12]See Cordes (1989).

specialized missions established R&D organizations called federally funded R&D centers (FFRDC), which they continue to support today.[13] In 1989, universities administered 18 of the 36 FFRDCs; these 18 FFRDCs received an estimated $3.6 billion in 1989 Federal obligations for R&D. This transfer of $3.6 billion from Federal agencies to university-affiliated FFRDCs for R&D represents a unique—if indirect—form of Federal support to science and engineering at U.S. universities. Researchers at university-affiliated FFRDCs often include faculty, academic nonfaculty, and graduate students, thereby providing opportunities for extensive interactions between researchers at FFRDCs and at universities.

Distribution of R&D Funds Among Specific Academic Institutions

Most academic R&D is concentrated in relatively few institutions. Of 3,400 higher education institutions in the U.S.,[14] the top 20 of them spent 35 percent of total academic R&D funds in 1987, and the top 100 institutions spent 83 percent of the total funds. (See text table 5-1 and appendix table 5-6.)

Industrial Support of R&D at Specific Academic Institutions[15]

Industry now supports over 6 percent of total academic R&D. While most of the industrial funds go to large, recognized research institutions, about a dozen academic institutions with relatively small R&D expenditures get more than 20 percent of their R&D funding from industry. These funding patterns partly reflect relationships that have developed between individual firms and schools.

In 1987, industry provided almost $800 million for academic R&D. Of the top 200 institutions ranked by their total academic R&D expenditures in 1987, the top 25 schools together received $260 million from industry, or 30 percent of the total support contributed by industry. The bottom 25 schools received $19 million, or 2.4 percent of total industry funds. The top 25 schools averaged $10.4 million each in industrial support; the lowest 25 schools averaged $0.8 million each. (See text table 5-2 and appendix tables 5-6 and 5-7.)

This distribution of industry funds follows an expected pattern. A more surprising finding is that industry was responsible for an average of 11.5 percent of the total R&D expenditures for the schools in ranks 176-200 in 1987, compared with a 5.5-percent share of the total R&D funds for the top 25 schools. Among the lower ranked academic institutions receiving relatively larger proportions of their R&D from industry, specialized smaller institutions tend to appear more often. These are often institutions with one R&D specialty that is closely linked with local industry.

Between 1980 and 1987, the number of schools receiving over 10 percent of their academic R&D support from industry increased from 24 to 49.[16] This increase may in part result from more institutions having separately reported industrial support data in 1987 than in 1980. (See text table 5-2.)

The increasing industry support for academic R&D may reflect increasing amounts of cooperative research activity between the two sectors. This conclusion is consistent with findings of increased industry-university coauthorship of research papers, discussed later in this chapter.

Academic R&D Expenditures by Field and Funding Source

The distribution of Federal and non-Federal funding of academic R&D in 1987 varied by field and subfield. (See appendix table 5-8.) For example, the Federal Government supported 66 percent of academic R&D expenditures in the medical sciences, but only 26 percent of academic R&D in the agricultural sciences; this latter figure reflects the traditionally strong role of states in supporting the agricultural sector.[17]

The majority of academic R&D expenditures in 1987 went to the life sciences, which accounted for 54 percent of total academic R&D expenditures, 52 percent of Federal academic R&D expenditures, and 56 percent of non-Federal academic R&D expenditures. (See appendix table 5-9.) The next largest block of academic R&D expenditures was for engineering, which had a 16-percent share in 1987.

Between 1977 and 1987, academic R&D expenditures for all fields combined grew at an average annual rate of

Text table 5-1. Distribution of R&D funds among academic institutions: 1987

Rank	Millions of dollars	Percentage of total
All institutions	12,082	100
Top 10	2,560	21
Top 20	4,233	35
Top 50	7,293	60
Top 100	9,981	83

See appendix table 5-6.

Science & Engineering Indicators—1989

[13] See chapter 4.

[14] The Carnegie Corporation classified 3,400 degree-granting institutions as higher education institutions in 1987. They include 4-year colleges and universities, specialized schools such as medical and law schools, 2-year community and junior colleges, and a few specialized institutions. Not included are more than 7,000 other postsecondary institutions (secretarial schools, auto repair schools, etc.).

[15] The corporate contributions to R&D may be understated in these data, since schools do not uniformly record and report corporate contributions.

[16] See NSB (1982), pp. 8-9.

[17] Of the $4.8 billion in non-Federal support for academic R&D in 1987, 18 percent went for agricultural sciences. The only subfield receiving a larger share of the non-Federal support for academic R&D was the medical sciences, with 21 percent. Only 4 percent of total Federal academic R&D funding was for agricultural sciences. (See discussion of state support for R&D in chapter 4.)

176-200	8	11	11.4	11.5

[1]Omits data from institutions not separately reporting industrial R&D funding and from institutions reporting no industrial support. Omitted 32 institutions in 1980 and 11 in 1987.

[2]Ranking is derived by sorting institutions into groups of 25, from highest R&D expenditures to lowest. See appendix table 5-7.

Science & Engineering Indicators—1989

5.4 percent in constant 1982 dollars. From 1986 to 1987, the rate increased to 7.1 percent. (See figure O-21 in Overview and appendix table 5-9.) Funding for computer science grew fastest during the decade, increasing at an average annual rate of 14 percent in constant dollars. R&D expenditures for computer science in 1987 were about 3 percent of total academic R&D. Engineering grew second fastest during the decade, at an average annual rate of 8 percent; for 1986 to 1987, the rate increased to 11 percent. Mathematical sciences, with 1.5 percent of 1987 academic R&D expenditures, grew third fastest, at an average annual rate of 7 percent between 1977 and 1987.

At the other end of the growth scale, the social sciences have barely increased in academic R&D expenditures since 1977, averaging annual increases of 0.5 percent in constant 1982 dollars and accounting for 4 percent of 1987 academic R&D funding.

Academic R&D Facilities and Instrumentation[18]

The country's research universities have experienced large increases in investment in academic R&D facilities and instrumentation during the 1980s.[19] Recent surveys indicate that, after an extended period of decreased support, steps are now being taken to meet needs in these areas.

While the terms "facilities" and "equipment" are defined specifically for each survey, in general, *facilities* come out of capital funds, are fixed items such as buildings, often cost millions of dollars, and are not included within R&D expenditures. *Equipment* and *instruments*, on the other hand, usually are movable, purchased with current funds, and included within R&D expenditures. Because the categories are not mutually exclusive, some large instrumentation systems could be classified as either facilities or equipment.

Facilities. In addition to the $12.1 billion that academic institutions spent for separately budgeted R&D activities in 1987, $1.8 billion was disbursed for capital investment in S/E facilities and fixed equipment to be used for R&D and instruction. In constant dollars, this represented an

[18]Data on facilities and instrumentation are taken primarily from the following three sources:

- *Academic Science/Engineering: R&D Funds, Fiscal Year 1987.* The term facilities as used in this survey stands for capital investment expenditures for S/E research or instruction at those universities and colleges spending $50,000 or more annually on separately budgeted R&D. See NSF (1989c).
- *Scientific and Engineering Research Facilities at Universities and Colleges: 1988.* Facilities are physical plant, including infrastructure (power), fixed equipment (benches, fume hoods), and nonfixed equipment costing more than $1 million. The survey also includes information on R&D space. See NSF (1988a), p. D-4 for definitions.
- *Academic Research Equipment in Selected Science/Engineering Fields: 1982-83 to 1985-86.* Equipment with an original purchase price of $10,000 to $1 million was included in this survey of academic departments covering the major S/E disciplines. See NSF (1988b), p. A-11 for definitions.

[19]The terms "instrumentation" and "equipment" are used interchangeably.

increase of 14 percent over 1986; the 1986 figure had in turn been an increase of 18 percent over 1985.

Total capital expenditures for academic S/E facilities (plant and fixed equipment) increased during the 1980s at an average annual rate of 7 percent in constant 1982 dollars. As noted above, recent increases have been even greater. (See figure 5-3 and appendix table 5-10.) Among the S/E fields, engineering has enjoyed the highest rate of growth—an average of 18 percent per year in constant 1982 dollars since 1980. Mathematical/computer sciences were second with 9-percent average annual growth between 1980 and 1987. (See appendix table 5-11.) By contrast, average annual increases between 1980 and 1987 were 0.3 percent for the environmental sciences and 2 percent for social sciences.

Non-Federal sources provide most of the funds for capital expenditures. Their proportion has been increasing—71 percent in 1970, 81 percent in 1980, 92 percent in 1987. Non-Federal sources, which include state and local governments, special bonds, donations, and other sources, grew an average of 9 percent per year in constant 1982 dollars between 1980 and 1987. Between 1985 and 1987, Federal spending for academic R&D facilities increased more than 50 percent in constant dollars, while non-Federal sources increased 33 percent.

Construction costs of academic S/E research facilities are expected to reach $3.4 billion in current dollars in 1988+1989, up from $2.1 billion in 1986+1987.[20] Between 1986 and 1989, these construction projects were expected to increase existing research space by 22 million square feet, an increase of 19 percent over space available in 1985.

New construction projects are increasingly expensive: in 1986+1987, for example, the cost of new academic R&D space in current dollars was $206 per square foot, compared to $287 per square foot in 1988+1989. (See appendix table 5-12.) Factors contributing to the markedly increased costs of facilities construction include the need for better data-handling capabilities as well as more stringent standards for animal facilities, toxic waste disposal, and biohazard control.

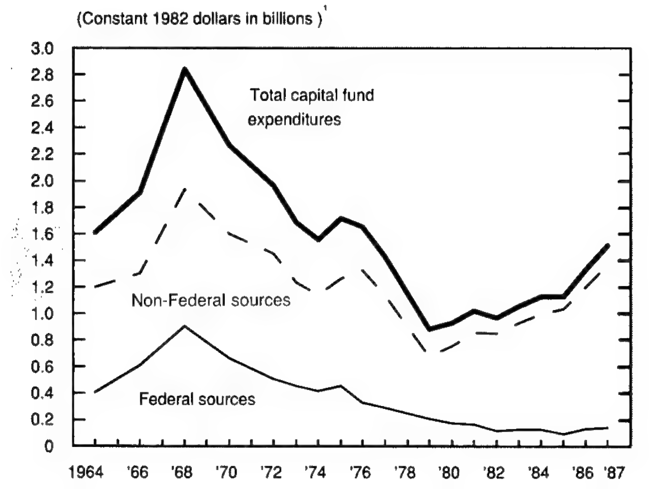
Despite the increased funding, there is a large estimated construction backlog as well as a backlog of academic research facilities that need renovation and repair.[21] Institutions are deferring an estimated $2.50 for every $1.00 of construction that was planned through 1989. They are also deferring about $3.60 in needed renovation and repair for every $1.00 spent.[22]

Instrumentation. Throughout the 1980s, U.S. academic institutions have invested heavily in R&D instruments. Results of a survey of academic research equipment in selected fields showed that approximately 40 percent of all instrument systems in research use in 1985/86 had been acquired in the previous 3 years, and about 25 percent of instrument systems in use in 1982/83 had been retired from research by 1985/86.[23] The median age of the national stock of instruments (both in-use and not in-use) in 1982/83 and 1985/86 was 5 years. However, the median age of state-of-the-art instruments was 2 years, indicating the rapid pace of technological change in research instrumentation.

In general, current fund expenditures[24] for academic research instrumentation have grown in the 1980s, except during the 1981-83 recession.[25] (See appendix table 5-13.) Annual growth during the 1980s averaged 8 percent for Federal support and 10 percent for non-Federal support in constant 1982 dollars. Federal support accounted for about two-thirds of total current fund expenditures for academic research equipment during the 1980s; this percentage varied widely among individual fields, however.

Funds for instruments for computer science and mathematical sciences grew fastest, each increasing in constant 1982 dollars by a factor of about four since 1980. Equipment funds for all other S/E fields combined increased by

Figure 5-3.
Federal and non-Federal capital fund expenditures for academic S/E: 1964-87



[1]GNP implicit price deflators were used to convert dollars to constant 1982 dollars.
See appendix table 5-10. *Science & Engineering Indicators—1989*

[20]Data are aggregated into 2-year units because the data are more stable and some data were only available aggregated for 1988 and 1989. See NSF (1988b). See also a parallel report on biomedical research facilities, NIH (1989).

[21]Association of Physical Plant Administrators (1989); NSF (1989d); and NSF (1988a).

[22]In response to this long-term problem, Congress passed the Academic Research Facilities Modernization Act of 1988 authorizing NSF to set up a competitive grant program for the repair, renovation, and, in exceptional cases, replacement of academic research facilities. NSF (1989d).

[23]Data for the physical sciences, computer science, and engineering were collected for 1982 and 1985; data for the agricultural, biological, and environmental sciences were collected for 1983 and 1986. Therefore, data from this survey refer to 1982/83 data and 1985/86 data. See NSF (1988b). Unless otherwise noted, data are for instruments costing from $10,000 to $1 million.

[24]Current funds—as opposed to capital funds—are those in the yearly operating budget for ongoing activities. Generally, academic institutions keep separate accounts for current and capital funds.

[25]Data used here are limited to funds for research instrumentation and do not include funds for instructional equipment.

less than a factor of two. Funds from non-Federal sources for social sciences instrumentation increased an average of 3.5 percent annually between 1980 and 1987, but this increase did not fully offset an average annual 6-percent decrease in Federal funding. Taking all fields together, current fund expenditures for purchasing instruments grew more slowly between 1986 and 1987 than between 1983 and 1986.

A special survey of academic departments to obtain information on instruments in selected fields shows increases in expenditures and in numbers of instruments. Between 1982/83 and 1985/86, the number of *in-use* academic R&D instrument systems costing between $10,000 and $1 million increased almost 50 percent—from 36,300 to 53,900—in the fields surveyed.[26] (See appendix table 5-14.)

The average price (corrected for inflation) of in-use instrument systems remained at about $36,000 between 1982/83 and 1985/86. The aggregate purchase price for these instruments increased from $1.3 billion in 1982/83 to $1.9 billion in 1985/86, corrected for inflation.[27] The most notable change was a 22-percent decrease in the average price of the in-use stock of instruments in computer science, dropping from $58,000 to $45,000.

Costs of purchasing and repairing instruments, corrected for inflation, increased between 1982/83 and 1985/86. (See appendix table 5-15.) Expenditures for purchasing new or used equipment increased by 48 percent, with such purchases accounting for 75 percent of total instrument costs in 1985/86. Maintenance and repair costs increased 26 percent, and accounted for 16 percent of departmental instrument-related expenditures in 1985/86. In contrast, expenditures for research-related computer services declined substantially during the 3-year interval.

Supercomputer Installations. Supercomputer installations are an indicator of a country's ability to do certain types of advanced research. The U.S. leads the world in numbers of supercomputer installations with 272 at the end of 1988. U.S. universities have about 20 percent of these U.S. supercomputers, with the remaining 80 percent divided evenly between industry and government. (See text table 5-3.) U.S. supercomputing capability has grown rapidly, increasing by 69 percent between 1986 and 1987, and by 33 percent between 1987 and 1988.

With 172 installations, Japan is second among world countries in number of supercomputer installations. In contrast to the distribution in the U.S., the Japanese industrial sector accounts for almost three-quarters of the country's supercomputer installations. U.S. manufacturers provided about 40 percent of the supercomputer facilities available in Japan in 1988; Japanese manufacturers provided the remaining 60 percent.[28]

[26]The *total* national stock of instruments includes instrument systems purchased but not yet in use, in-use instruments, and inactive or inoperable but not discarded systems. Total national stock increased from 46,500 instruments to 62,200 instrument systems between 1982/83 and 1985/86. Of the 62,200 instrument systems, 2 percent were purchased but not yet in use, and 15 percent were inactive or inoperable. See NSF (1988b) for further breakdowns of these data.

[27]The aggregate purchase price for all systems (in-use and not in-use) costing between $10,000 and $1 million was $1.6 billion in 1982/83 and $2.2 billion in 1985/86, corrected for inflation. In addition, there was another $0.7 billion in 1982/83 and $1.1 billion in 1985/86 worth of large instrument systems, generally over $1 million each; most of these systems were for general-purpose research computer centers and high-energy physics systems. These large systems are not discussed here or included in totals.

Library Costs for Serials[29]

Like facilities and instrumentation, libraries are crucial to maintaining academic R&D capability. The rapidly in-

[28]As of 1988, based on cumulative data, U.S.-manufactured supercomputers were distributed around the world as follows: U.S., 52 percent; Japan, 14 percent; other countries, 34 percent.

[29]The terms "serials" and "periodicals" are used interchangeably. The term chosen is the one used by the source of the information being discussed.

Text table 5-3. Cumulative number of general-purpose supercomputer installations in Japan and the U.S.: 1983-88

	Japan				United States[1]			
	Total	Universities	Government	Industry	Total	Universities	Government	Industry
1983	5	2	0	3	46	3	23	20
1984	13	3	3	7	53	5	26	22
1985	27	6	6	15	89	14	39	36
1986	58	14	9	35	121	14	57	50
1987	121	24	13	84	204	36	79	89
1988	172	33	15	124	272	57	107	108

[1]Data are for U.S. vendors only; they have provided almost all supercomputers used in the U.S.

Note: These data are somewhat uncertain because definitions of supercomputers change and because some installations counted here are no longer in use.

SOURCES: United States: NSF, Division of Advanced Scientific Computing; Japan: Tokyo Office of the U.S. NSF, Report Memorandum #184, August 10, 1989.

Science & Engineering Indicators—1989

creasing costs of serials—especially in the areas of science, technology, and medicine—have put financial pressure on research libraries and generated concern throughout the scientific community.[30]

Costs Highest for Science Serials. Periodicals in the sciences, technology, and medicine tend to be more expensive than serials in most other fields. (See appendix table 5-16.) For example, the average 1989 subscription price was $308 for the 10 library categories of science, compared with $140 for the 10 categories of social science.[31] These prices were based on a data base of approximately 55,000 domestic and foreign titles. A different data base, consisting of a fixed set of 3,900 domestic periodicals, shows that science-related periodicals have increased in price during the 1980s more rapidly than periodicals in other fields.[32]

Costs of Foreign Periodicals Also Rise. Prices of serials published in foreign countries have increased rapidly, partly because of the weakening dollar compared to foreign currencies. This increase, however, may have temporarily slowed. The average 1-year subscription rate for foreign titles (all fields) increased 3 percent between 1988 and 1989, compared with 17 percent and 19 percent for the two previous annual intervals.[33] In 1989, average subscription prices (all fields) of U.S. and foreign serials were similar: $148 for domestic titles and $143 for foreign titles.

High Costs Require Hard Choices. As a major source of information about university research libraries, the Association of Research Libraries (ARL) has issued a report that relates the pricing policies of several major scientific publishers to increases in serials prices.[34] Between 1986 and 1988, expenditures for total serials at the ARL member libraries (107 university research libraries and 12 independent research libraries) increased 30 percent, but the number of current serials remained constant and numbers of monographs (books) purchased were cut by 15 percent. ARL does not have data to indicate whether prices of science-related serials were a major factor behind these findings.

Current serials have remained about 20 percent of expenditures at ARL libraries throughout the decade in the median university library.[35] However, overall library expenditures have been increasing faster than inflation during the decade. In the 1980s, library investment in automation and communication equipment has been a factor in these increasing costs.

DOCTORAL SCIENTISTS AND ENGINEERS ACTIVE IN RESEARCH

This section describes characteristics of doctoral scientists and engineers who work in academic institutions and whose primary or secondary work activity is R&D (basic research, applied research, or development).[36] Data about

[30]See Kingson (1989); Kalfus (1989); and Koshland (1989).
[31]Young (1989).
[32]Young and Carpenter (1989).
[33]Young (1989).

[34]See ARL (1989b). The report also observes that the increased size of many journals affects prices.
[35]See ARL (1989a).
[36]Data in this section come from the Survey of Doctorate Recipients conducted biennially by the National Research Council (NRC) for NSF. In this section, "academic institutions" refer to 4-year colleges, universities, and medical schools, as identified by the respondents. Federally funded research and development centers comprise all FFRDCs.

A recent broad assessment of the National Science Foundation's surveys of scientists and engineers (NRC, 1989) has noted limitations of this doctorate survey and has recommended improvements.

Examples of Library Expenditures for Science Serials

The price increases in science-related serials are of major concern to librarians and researchers because these serials are a significant portion of the serials and monograph acquisitions budgets of research libraries. However, because libraries usually have not classified their serials and monograph expenditures into science and nonscience categories, there are no national data on their relative expenditures for science-related and other periodicals.

Several studies are under way to address this data need. Results suggest that science-related serials constitute over 50 percent of the current serials budgets of typical research libraries.

- A study at the University of Nebraska at Lincoln showed that 67 percent of serials expenditures for 1988/89 were in the science, agriculture, technology, and medical categories, while these four categories accounted for a much lower 45 percent of the *number* of serials purchased. (Information provided by Kent Hendrickson, Dean of Libraries of the University of Nebraska, Lincoln; personal communications, August 1989.)

  (Dean Hendrickson also reported that expenditures for science-related serials constituted between 58 percent and 67 percent of serials expenditures at his libraries between 1980 and 1987. Cancelled subscriptions to current serials during that period totaled $250,000 out of an annual current serials budget of about $2 million.)

- Louisiana State University also spent more than half (55 percent) of its 1985/86 serials budget for science-related serials. (Information provided by Charles Hamaker, Louisiana State University; personal communication, August 1989.)

- In analyzing serials prices, nine Midwestern academic research libraries found that 72 percent of serials whose subscriptions cost $200 or more were in the science, agriculture, technology, and medical categories. Those four categories accounted for over 85 percent of the expenditures for the $200-plus subscriptions at these libraries.

the overall doctoral basic research workforce are included to provide a perspective on academic basic researchers. The discussion is limited to doctoral researchers because they have major roles in academic R&D activities.

Numbers of Academic Researchers in Various Fields

In 1987, there were 155,000 doctoral scientists and engineers whose primary or secondary work activity was academic R&D.[37] (See appendix table 5-17.) They represented 37 percent of employed S/E doctorates in the United States in 1987. Scientists made up 88 percent and engineers 12 percent of the total; these proportions were about the same as in 1977. (See figure 5-4.) Life scientists were the largest single group of doctoral scientists and engineers in academic R&D in 1987, constituting 34 percent of the total.

The numbers of doctoral scientists and engineers in academic R&D increased by 65 percent during the 1977-87 decade. Growth appeared to be especially rapid between 1985 and 1987.[38] (See figures 5-5 and 5-6 and appendix table 5-17.) Over the 1977-87 decade, the highest rate of increase occurred among computer scientists, whose numbers tripled from 1,200 to 3,500.

Women in Academic R&D. While women increased their percentages in all fields of academic R&D in recent years, some fields still have relatively few women. (See figure 5-7 and appendix table 5-18.) Overall, the percentage of women doctoral scientists and engineers in academic R&D increased from 10 percent in 1977 to 16 percent

[37]The 1987 survey question on primary and secondary work activity reads: "From the activities listed below, select your primary and secondary work activities . . . in terms of time devoted during a typical week." Because many faculty members who devote substantial time to R&D often consider another activity (for example, teaching) to be their primary work activity, those survey respondents who selected academic R&D as their primary or secondary work activity are included here. Inclusion of both sets of respondents results in approximately twice as many as when only primary work activity respondents are counted, and ensures that all individuals involved in academic R&D are counted.

Data in some of the appendix tables differ from the comparable data in *Science & Engineering Indicators—1987* because the latter used a somewhat different set of respondents.

[38]The 1987 wording of the survey question about work activity involving basic research and applied research differed slightly from that in 1985. The 1987 survey defined basic research as "study directed toward gaining scientific knowledge primarily for its own sake." Applied research was "study directed toward gaining scientific knowledge in an effort to meet a recognized need." Earlier surveys had no clarifying definitions. Because of this difference, data from the 2 years may not be exactly comparable. However, a similar sharp increase between 1985 and 1987 was seen in numbers of academic R&D researchers when the responses were analyzed only by primary work activity. In the analysis by primary work activity, half of the increase was accounted for by decreases in the "other" and "teaching" categories; the remainder was accounted for by the increase in total doctorates employed in academic S/E, all of whom apparently went into R&D. A similar analysis was not available for primary and secondary work activities combined.

Figure 5-4.
Distribution of doctoral scientists and engineers in academic R&D, by field: 1977 and 1987

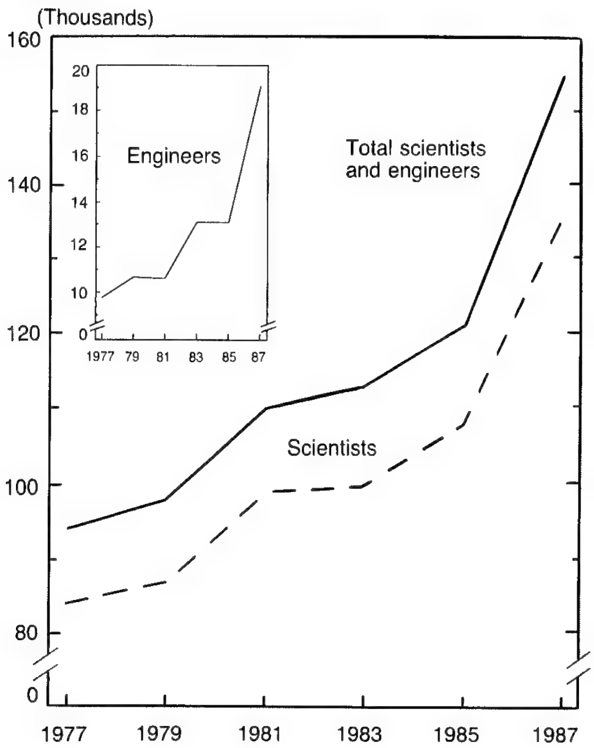
Figure 5-6.
Doctoral scientists and engineers in academic R&D: 1977-87



See appendix table 5-17. *Science & Engineering Indicators—1989*

in 1987. In the fast-growing computer science field, the proportion of women increased from 5.3 percent in 1977 to 10 percent in 1987. Among the social sciences, which also grew rapidly during the decade, the proportion who were women increased from 12 percent in 1977 to 20 percent in 1987. The proportion of women doctorates in academic R&D in the various fields approximately reflects their representation in the doctoral S/E workforce in those fields.[39]

Minorities in Academic R&D. Whites still make up almost 90 percent of the academic R&D workforce, although racial minorities and Hispanics increased their representation during the 1977-87 decade.[40] Except for Asians, however, overall percentages of minorities in academic R&D remained below 2 percent in 1987. (See appendix table 5-18.) Blacks increased their overall percentage in academic R&D from 0.8 percent to 1.4 percent during the decade. In 1987, they were more heavily represented in the social sciences and the life sciences than in other fields.

Black women showed especially interesting gains. In 1987, 31 percent of black doctoral scientists in academic R&D were women.[41] This figure is substantially higher than the 18-percent figure for Asians and for whites. (See figure 5-7.) This higher representation of black women was also evident in 1977. The number of black women doctoral scientists increased from 131 to 611 over the 10-year period, an almost fivefold increase; the number of black men scientists doubled, reaching 1,381.

Hispanics accounted for 1.7 percent of S/E doctorates in academic R&D in 1987, compared with 1.0 percent in 1977. As with blacks, they are most heavily represented in the life sciences and social sciences. Hispanics' greatest percentage increase occurred in engineering, where their numbers rose from 69 in 1977 to 385 in 1987.

Asian representation in academic R&D rose to 9 percent in 1987. (See appendix table 5-18.) Among major fields, they were most heavily represented in engineering—18 percent in 1987. Among Asians, 14 percent were women, whose shares by field were generally similar to those for white women. (See figure 5-7.) The major exception was physical sciences: 13 percent of Asian physical scientists were women, in contrast to 7 percent of white physical scientists.

Academic and Nonacademic Doctoral S/E Basic Researchers

Employment by Sector. The total number of doctoral S/E basic researchers increased from 88,000 in 1977 to 133,000 in 1987, a 51-percent increase.[42] Nonacademic basic researchers increased 30 percent, from 21,900 to 28,600. With a 48-percent increase in basic researchers, nonprofit organizations showed the largest increase among nonacademic sectors. (See appendix table 5-19.)

Almost 80 percent of doctoral scientists and engineers in basic research in 1987 were also in academia. Thus, most of the broad demographic characteristics of the two groups are similar in terms of gender, race/ethnicity, and distribution by field. Moreover, academia employed almost all of the doctoral basic researchers in some fields—e.g., mathematics, 97 percent; sociology/anthropology, 97 percent; and economics, 93 percent.

Industry employed the next largest percentage of doctoral basic researchers—8.6 percent. (See figure 5-8 and appendix table 5-19.) Although it employed less than 10 percent overall of basic researchers, the industrial sector employed 19 percent of all engineers doing basic research and 25 percent of the computer scientists in basic research in 1987. Industry also more than doubled its number of life scientist doctorates in basic research between 1977 and 1987 (from 1,400 to 3,100). This increase probably reflects recent industrial emphasis on development of biotechnology products.

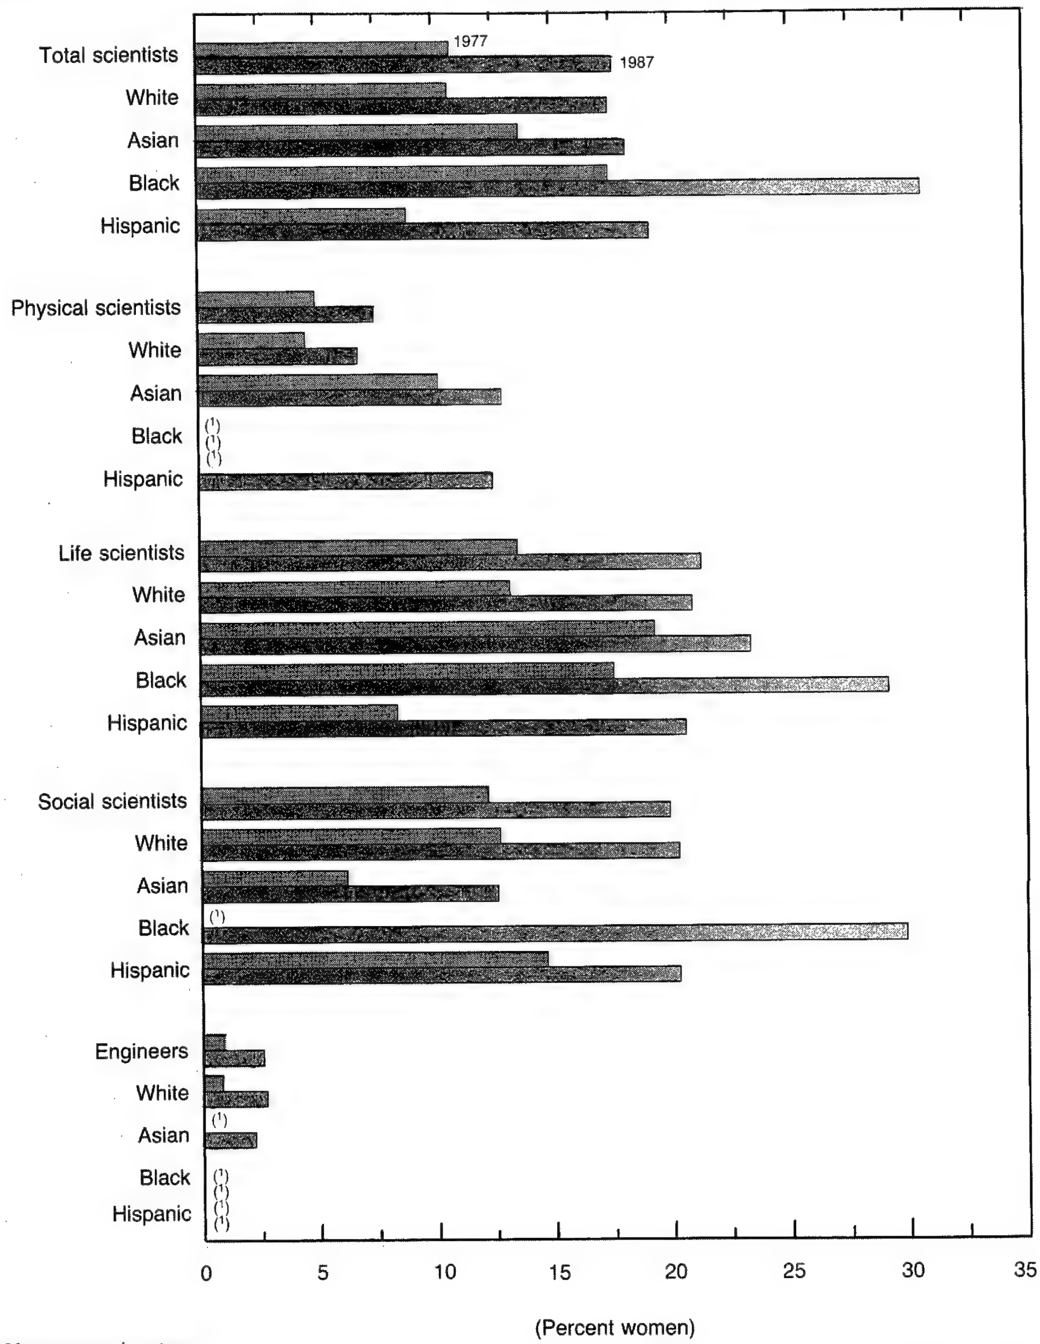
[39]See chapter 3 for the distribution of women doctorates by field in the total S/E workforce.

[40]Hispanics include members of various racial groups.

[41]Only doctoral *scientists*, rather than scientists and engineers, are discussed here, since there were fewer than 20 black women doctoral engineers in 1987.

[42]As with the academic R&D doctoral personnel data, these 1987 figures are not necessarily exactly comparable to data from earlier years because of changes in the 1987 survey question on character of work.

Figure 5-7.
Percentage of women doctoral scientists and engineers in academic R&D, by race/ethnicity and field: 1977 and 1987



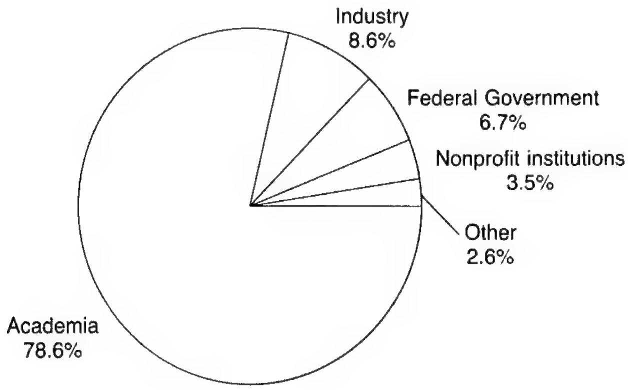
[1]Fewer than 20 women are in category.
See appendix table 5-18.

Science & Engineering Indicators—1989

Minorities and Women in Basic Research. Among doctoral basic researchers in 1987, 1.1 percent were black; 25 percent of these were women. (See appendix table 5-20.) However, the absolute numbers of black basic researchers remained low (1,277 men and 416 women in 1987). Asians made up 6.8 percent of the doctorate S/E basic research workforce in 1987; 15 percent of the Asians were women. Asians are especially prevalent in engineering, where they accounted for 26 percent of basic researchers in 1987; the comparable figure in 1977 was 15 percent.

Employment sectors vary in their proportions of women and minorities doing basic research, but the overall numbers and proportions of women and minorities in the sectors increased between 1977 and 1987. For example,

Figure 5-8.
Employment of doctoral scientists and engineers in basic research, by sector: 1987



See appendix table 5-19. *Science & Engineering Indicators—1989*

over the decade, the proportion of doctoral basic researchers who are women increased:

- In academia, from 11 percent to 17 percent; and
- In the Federal Government, from 7.3 percent to 12 percent.

Also in the Federal Government, the percentage of black doctorates in S/E basic research increased from 1.2 percent to 2.1 percent, or from 85 to 188 individuals.

With Asians comprising 14 percent of its doctoral basic researchers, industry had a higher Asian representation than any other sector in 1987. Also, industry increased its percentage of basic researchers who are women from 5.5 percent in 1977 to 12 percent in 1987. As in academic R&D, women were especially prevalent in life sciences: 21 percent of industrial life sciences basic researchers were women in 1987, compared with 10 percent a decade earlier.

Retention of Doctoral S/E Researchers in Employment Sectors and Research Activities[43]

Retention in Employment Sectors.[44] The largest percentage of doctoral scientists and engineers in research who are going to leave their employing sector do so during their initial 2 years in that sector; longitudinal surveys show that decreasing percentages leave during subsequent time intervals. (See figure 5-9 and appendix table 5-21.) While 7 percent of male doctorates in academic R&D in 1973 had left that sector 2 years later, only 21 percent had left after 14 years.[45] In other words, 79 percent of those working in academic R&D in 1973 were still in academia 14 years later (although not necessarily in R&D). The retention rates for women follow similar patterns, although the rates are somewhat lower than for men.[46]

[43]These data come from the NRC/NSF Survey of Doctorate Recipients data base. A weighted sample of new doctorates from each year enter the survey, and are surveyed in subsequent years. No new entrants are added to an earlier year's cohort. Thus, attrition occurs. The analysis here was based on respondents who answered the NRC/NSF Survey of Doctorate Recipients questionnaire in both years of the interval being analyzed. Because NRC used varied sampling strategies over the years, it is not very useful to compare actual numbers of respondents at the different times. However, there were 15,000 matched respondents for 1973 and 1975; 6,000 of them also matched for 1973 and 1987.

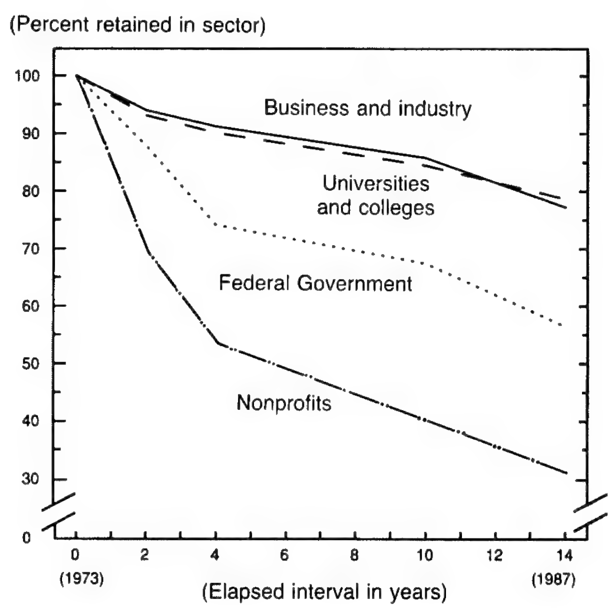
[44]For this and the following subsection only, the term "researcher" refers to doctoral researchers in nonacademic basic research or in academic R&D.

[45]Fourteen years was the longest time interval available in analysis of longitudinal survey data. The NRC/NSF Survey of Doctorate Recipients data base was used to follow movement among repeat responders. No corrections were made for nonresponders.

The estimates of retention have some uncertainty. Data from the 2-year initial time period probably overestimate retention rates, because the baseline sample contains people who have just started a job as well as those who have been at a position or with an employer for longer time periods. By contrast, doctorates in the 10- and 14-year samples have been in the same or related positions for at least as long as the time interval, and apparently are more stable in their positions. It is also possible that those who have not changed employers are more likely to receive subsequent questionnaires (because they have not changed addresses) than researchers who have moved, again leading to a possible overestimate of retention rates.

[46]Because of the much larger numbers of males compared with females in the doctoral S/E workforce, the totals are largely determined by the male pattern. Moreover, the retention rates vary the most in those categories that contain fewer individuals—for example, women in the nonprofit or industry sector during the 1970s.

Figure 5-9.
Retention of doctoral scientists and engineers in employment sectors, by number of elapsed years



Note: Data are for men, although women show similar results.
See appendix table 5-21. *Science & Engineering Indicators—1989*

Overall, the retention rates are generally similar when the same number of elapsed years (i.e., 2, 4, or 10 years) are compared for different calendar year intervals, for example, 1973-77 compared to 1983-87. Retention rates vary greatly among sectors, with the industrial and academic sectors showing rates very similar to each other, and both considerably higher than those of the Federal Government and nonprofit organizations. (See figure 5-9.) Relatively little movement of researchers occurs between the industrial and academic sectors, with 2-percent to 3-percent movement in either direction during selected 2-year intervals.[47] However, because there are many more researchers in the academic sector, this rate suggests that much larger numbers of academic researchers move to industry than vice versa.

Retention of Doctoral Scientists and Engineers in Research. Individuals were considered to have stayed in research from $time_1$ to $time_2$ if they were in academic R&D or nonacademic basic research when surveyed at both $time_1$ and $time_2$. Approximately 20 percent to 30 percent of researchers in a given year are no longer working at these research activities 2 years later. (See text table 5-4 and appendix table 5-22.) However, the rate at which scientists and engineers leave these activities decreases over longer time intervals. Thus, while 70 percent to 80 percent stay in research over 2-year periods, 60 percent of men and 55 percent of women were still doing nonacademic basic research or academic R&D when surveyed after 14 years (1973-87).

These findings suggest there is a large turnover of doctoral level basic researchers soon after they begin research.

[47]NSB (1987), p. 94.

Text table 5-4. Retention of doctoral scientists and engineers in research for various time intervals since 1973

	Elapsed time	Retention in research: Male	Retention in research: Female
	—Years—	—Percent—	
1973-75	2	80	79
1973-77	4	65	61
1973-83	10	58	51
1973-87	14	60	55
1977-79	2	74	72
1977-87	10	66	63
1983-85	2	75	74
1983-87	4	78	75
1985-87	2	83	81

Note: Data are for doctoral scientists and engineers whose primary or secondary work activity was nonacademic basic research or academic R&D in the first year of a time interval, and who also responded to the Survey of Doctorate Recipients in the final year of an indicated time interval.

See appendix table 5-22.

Science & Engineering Indicators—1989

Recent Ph.D.s in postdoctoral positions may be unable to get another research position; faculty who do not get tenure may move to positions where academic R&D or nonacademic basic research is no longer their primary or secondary work activity; some scientists and engineers may find they do not want to continue in academic R&D or nonacademic basic research.

A larger proportion of doctoral scientists and engineers apparently stayed in research in the 1980s compared with the 1970s. (See text table 5-4 and appendix table 5-22.) For example, the retention rates between the 4-year interval from 1983 to 1987 were higher than the rates between 1973 and 1977. The same qualitative finding holds for 1977 to 1987 compared with the earlier period 1973 to 1983. These results contrast with those discussed earlier for movements between sectors, where retention rates were largely independent of calendar time.

OUTPUTS OF ACADEMIC R&D: SCIENTIFIC LITERATURE, PATENTS, AND PRODUCTS[48]

The primary output of university research is new knowledge, usually measured by various types of publication counts. As an indicator of the impact that a publication has on other research, academic researchers often use citation data. Based on publication counts, U.S. academic institutions continue to produce a substantial share of the world's new S/E knowledge—albeit with increased interactions with researchers from other sectors and countries.

Bibliometrics is the generic term to describe data about publications. This section uses bibliometric data to explore trends in U.S. and world publication and citation data.[49] For example, bibliometric data permit tracking of patterns of collaboration among countries, among U.S. employment sectors, and among individual researchers. Current data show that:

- The U.S. is maintaining its large share of world science and engineering literature;
- Coauthorship is rapidly increasing among individuals, countries, and sectors; and
- There have been some specific changes over the past decade in intercountry citation patterns, although the overall patterns have remained unchanged.

[48]In this section, academic institutions are essentially *all* U.S. educational institutions, including high schools. The terms "universities" and "academic institutions" are used interchangeably in this section. In this section, federally funded research and development centers comprise all FFRDCs, including those administered by colleges and universities.

[49]The publication data discussed here are taken from science literature indicators developed by Computer Horizons, Inc. (CHI), for the National Science Foundation. The CHI tabulations are derived from the Science Citation Index data base created by the Institute for Scientific Information. CHI has developed several major data bases. One covers the articles, notes, and reviews in a fixed journal set covering approximately 2,100 of the most significant S/E journals from 1973. A second data base covers articles, notes, and reviews in a fixed journal set of over 3,200 of the most influential journals from 1981 forward.

Throughout this section, the terms "papers," "articles," and "publications" are used interchangeably, and refer to the articles, notes, and reviews in the CHI bibliometric data bases.

University *patents* measure a different type of knowledge. A recent sharp increase in university patenting is an indicator of the expanding role played by academic R&D in technology development.

World S/E Literature: Comparisons and Interactions[50]

U.S. Share of World S/E Literature. Bibliometric data provide one way of looking at U.S. S/E activity in relation to that of other countries. In 1986, U.S. publications accounted for 36 percent of world publications in science and engineering, a figure that has been approximately constant since 1973 and very constant since 1981. (See appendix tables 5-23 and 5-24.) In all fields, the U.S. has a greater percentage of world publications than does any other country. The U.S. produces:

- 22 percent of the world literature in chemistry,
- 30 percent of physics publications, and
- Between 37 percent and 43 percent of the literature in the other major fields.

However, the U.S. world shares in mathematics, engineering/technology, and biology have dropped somewhat since 1973. (See text table O-1 in Overview and appendix table 5-23.) Interpretation of changes in other fields is uncertain because U.S. shares in all fields showed decreases when the number of journals analyzed was expanded by 50 percent in 1981.

Foreign Country Shares of World Literature. Among foreign countries, the United Kingdom, USSR, and Japan each contributed about 8 percent of world science and engineering literature in 1986, but the fields in which they contributed their largest shares differed. (See appendix table 5-25.) The United Kingdom made its greatest contributions in clinical medicine and biology (10 percent of world literature); the USSR provided 15 percent of world literature in both physics and chemistry; and Japan accounted for 13 percent of engineering/technology literature. One of the more notable changes in world shares is Japan's increase in world share of engineering/technology literature—from 9 percent in 1981 to 13 percent in 1986.[51]

Multi-Authored Papers. An ongoing increase in the average number of authors per paper suggests an increase in cooperation among scientists and engineers. Between 1973 and 1986, the average number of authors on world S/E publications increased from 2.3 to 3.0. (See appendix table 5-26.) Concurrently, the percentage of single-author papers decreased from 33 percent in 1973 to 19 percent in 1986. And, during the same time period, the overall percentage of S/E publications with four or more authors increased from 15 percent to 31 percent. (See figure 5-10.)

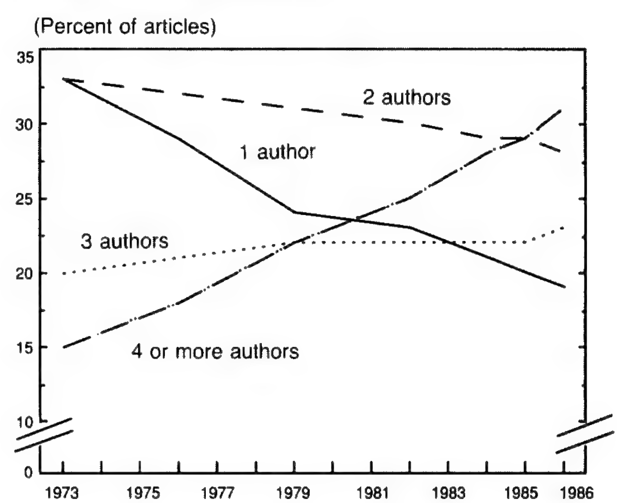
This trend toward more multi-authored papers may signal greater cooperation among individuals and groups, a move toward larger research groups, or increasing amounts of "big science." The trend might also reflect simply a tendency to give authorship to more contributors than in previous years.

The author distribution on mathematics papers contrasts strongly with that for other fields. Only 1 percent of mathematics publications in 1986 had four or more authors and 62 percent were single-author papers. These data suggest that mathematics research is a less collaborative activity than research in other fields.

International Coauthorship. Scientists and engineers throughout the world are increasingly coauthoring papers with researchers from other countries. In 1976, 4.0 percent of world science and engineering publications listed authors from more than one country; by 1986, this figure had increased to 7.5 percent. (See appendix table 5-27.)

S/E fields vary in degree of international copublication. At 13 percent, mathematics had the highest percentage of internationally coauthored articles in 1986—a somewhat surprising finding, given that the majority of mathematics papers have only one author. Earth/space sciences was

Figure 5-10.
Percentage of world S/E publications with 1, 2, 3, and 4 or more authors: 1973-86



See appendix table 5-26. *Science & Engineering Indicators—1989*

[50]These data are based on articles, notes, and reviews in journals from the 1973 and 1981 Science Citation Index Corporate Tapes. Articles written by researchers from more than one country are prorated across the *number of institutions involved from each country*, regardless of number of individual authors. For example, if an article has authors from two institutions in France and one institution from the U.S., it is counted as two-thirds of an article for France and one-third of an article for the United States. Articles attributed to U.S. sectors are similarly prorated. For some tabulations, articles are credited to a country, sector, etc., if at least one author is from the place of interest.

[51]For extensive bibliometric data for many of the world's countries, see Schubert, Glänzel, and Braun (1989). Their country publication shares are similar to those reported here.

second with 12 percent of papers internationally coauthored, and physics was third with 10 percent.[52] International collaborations at large-scale facilities for physics and astronomy research may contribute to the international character of these research fields.[53]

There has been an overall increase in U.S. international coauthorship. In 1986, 10.2 percent of publications with at least one U.S. author were internationally coauthored, up from 5.6 percent in 1976. (See text table 5-5, figure O-17 in Overview, and appendix table 5-28.)[54] This rise was apparent among all U.S. employment sectors. (See appendix table 5-29.) Notwithstanding this steady increase, the U.S. percentage of internationally coauthored papers is still relatively low compared with that of various Western countries.

Japan and the USSR, like the United States, also show relatively low—but increasing—percentages of international coauthorship. (See figure O-17 in Overview and appendix table 5-28.) In 1986, 7.5 percent of articles with at least one Japanese author were internationally coauthored; over half of these were coauthored with the United States, and the next largest percentage with West Germany. In 1986, 3.3 percent of publications with at least one author from the USSR were internationally coauthored, primarily with East Germany and the rest of Eastern Europe. Only 0.4 percent of the USSR articles were written with U.S. researchers.

Text table 5-5. Internationally coauthored articles for selected countries: 1976 and 1986

	1976	1986
	— Percent[1] —	
West Germany	9.7	20.9
United Kingdom	10.0	16.6
Canada	12.4	19.4
France	10.3	21.3
USSR	2.0	3.3
United States	5.6	10.2
Japan	3.5	7.5

[1]Internationally coauthored articles are expressed as a percentage of all articles with at least one author from the country.

See figure O-17 in Overview and appendix table 5-28.

Science & Engineering Indicators—1989

U.S. Sector Interactions in S/E Publications

U.S. Authorship and Coauthorship by Sector.[55] The academic sector is responsible for over two-thirds of U.S. science and engineering publications. Of the 137,770 U.S. S/E publications in 1986, universities accounted for 70 percent. (See appendix table 5-30.) These proportions are about the same as they were in 1976.

By field, academic institutions in 1986 accounted for between 60 percent and 80 percent of publications in all fields except mathematics and engineering/technology. (See appendix table 5-30.) In mathematics, academic institutions were responsible for a far higher share—over 90 percent of publications in 1986. In engineering/technol-percent of publications in 1986. In engineering/technology, they were responsible for 55 percent of publications; this was a considerable increase over their 40-percent share in 1976. (Over the same period, the industry share of engineering/technology publications dropped from 39 percent to 26 percent.)

A trend of increasing cross-sector coauthorship suggests there is increased research cooperation among U.S. employment sectors. (See appendix table 5-31.) For example, between 1973 and 1986, industry showed a substantial increase—from 17 percent to 35 percent—in the proportion of papers it coauthored with other sectors. The various nonacademic sectors publish more frequently with the academic sector than with each other. The proportions of papers coauthored with universities has risen reasonably steadily since 1973. (See figure 5-11.) By 1986, academic researchers were coauthors on approximately 30 percent to 50 percent of papers from each of the other sectors.

University-Industry Coauthorship. Trends in university-industry coauthorship were analyzed to determine whether this indicator was consistent with other evidence of increased interaction between these two sectors. Overall, 28 percent of articles with at least one industry author were coauthored with a university author in 1986, compared with the 1976 figure of 15 percent. By field, the percentage of industry articles coauthored with university authors in 1986 ranged from a low of 18 percent in chemistry to approximately 40 percent in the three life sciences. (See figure O-26 in Overview and appendix table 5-32.)

From the academic sector's viewpoint, fewer than 4 percent of articles with one or more academic authors were coauthored with industry authors in 1986. (The percentage was even lower in 1976.) Universities coauthored more with nonprofits (7.4 percent) and government (9.6 percent) than with industry or FFRDCs in 1986.

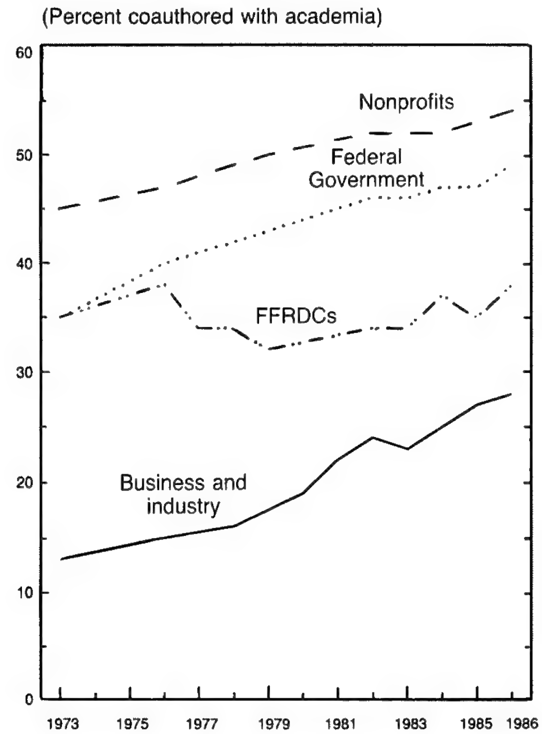
[52]Patterns of U.S. international coauthorship are similar to those worldwide. In 1986, U.S. researchers published most with foreign authors in mathematics (19 percent of U.S.-authored mathematics papers), earth/space sciences (16 percent), and physics (15.5 percent). (Data provided by CHI.)

[53]See Ailes, Coward, Owens, et al. (1988) for a discussion of large-scale research facilities in the U.S., Western Europe, and Japan. Examples are Fermilab in the U.S. and Centre Européen pour la Recherche Nucléaire (CERN) in Geneva for high-energy and particle physics; the Joint European Torus for atomic energy, and the European Molecular Biology Laboratory.

[54]Appendix tables 5-27 and 5-28 appear to show inconsistent degrees of international coauthorship. However, in appendix table 5-28, publications are counted at least twice, since they are counted for *each* author country. Appendix table 5-27 uses actual numbers of publications.

[55]See footnote 50.

Figure 5-11.
Proportion of U.S. S/E articles coauthored with U.S. academic institutions, by sector: 1973-86



Note: An article is attributed to a sector if one or more authors are from the sector.
See appendix table 5-31. *Science & Engineering Indicators—1989*

Citation Analysis in the Scientific Literature[56]

Authors cite each other's papers for many reasons, but analysts generally assume that rates of citation provide some measure of the quality, relevance, or interest—the impact—of the cited papers.[57] Analysts also use citation data to provide information on how various science and engineering fields and subfields may be related to each other.

[56]This analysis uses a methodology designed to minimize the spurious effects that occur because authors tend to cite their own country and sector much more when citing recent papers than when citing papers several years old. The cross-sector and cross-country citation analyses employed here were performed using a 2-year-lag, 3-year rolling cycle. This approach excludes cited papers from either the same year as the citing paper or from the immediate prior year, but uses citations from the previous 3 years. For example, if 1984 is the citing year, 1980-82 are the cited years. While this approach allows analysis of temporal trends, it is not useful for quickly detecting "hot" research areas.

[57]See Cozzens (1989), Lederman (1987), and OTA (1986) for discussions about what citation data mean. Cozzens divides citations into two broad categories: citations that bolster the findings and conclusions of the citing paper, and those whose purpose is to give credit to the work of previous researchers.

U.S. References to Foreign Countries. Approximately 29 percent of references[58] in U.S. science and engineering papers are to foreign papers, a value that has persisted for the past decade. (See text table 5-6 and appendix table 5-33.) However, some notable changes for specific fields and countries have occurred. Over the 1977-86 period, U.S. publications decreased the percentage of their references to United Kingdom papers in all major fields. By contrast, U.S. authors increasingly cited papers from France, West Germany, and Japan. Although the share of Japanese references in U.S. papers increased more than a percentage point, Japanese papers still constitute a small share—3.5 percent—of total references in U.S. papers.

In general, citation patterns for individual fields follow those for all fields combined. Physics shows the greatest change; in 1977, foreign physics papers constituted 31 percent of physics references in U.S. papers, a percentage that had increased to 36 percent by 1986. Further analysis of this change shows that U.S. papers increased the number of citations to foreign physics papers faster than they increased the number of citations to U.S. physics papers.

Citation Patterns Between U.S. and Foreign Articles. In all fields combined, U.S. articles tend to cite U.S. publications almost twice as often as expected and to cite non-U.S. publications about half as often as expected, as estimated by relative citation ratios.[59] (See appendix table 5-34.) In other words, U.S. articles tend to *overcite* U.S. publications and to *undercite* non-U.S. publications. Foreign researchers cite U.S. papers in all fields combined exactly as frequently as predicted by the U.S. share of world literature: the relative citation ratio is 1.0. The relative citation ratios were surprisingly constant between 1977 and 1986, indicating little change in the relative amounts of attention that the citing authors devoted to the various cited categories.

The level of citation of U.S. papers suggests that U.S. researchers exert a substantial impact on foreign S/E publications. Since foreign papers for all fields combined cite U.S. papers as frequently as statistically expected, and the U.S. produces about 35 percent of the world S/E literature,

[58]The terms "citation" and "reference" are used interchangeably.

[59]Relative citation ratios (also called relative citation indexes) provide information on the relative impact of the cited papers. A relative citation ratio—for example, for the U.S. citing of French chemistry papers—is calculated as follows:

$$\frac{\dfrac{\text{Number of citations to French chemistry papers in U.S. citing publications}}{\text{Total number of chemistry citations in U.S. citing publications}}}{\dfrac{\text{Total number of published chemistry papers from France}}{\text{Total number of published chemistry papers in world}}}$$

If the ratio is greater than 1, the U.S. is citing French chemistry papers more than would be expected on statistical grounds. Essentially, the relative citation ratio measures the extent to which cited papers are getting more or less than their statistical share of attention as measured by citations.

Relative citation ratios can be subtly misinterpreted. For example, the smaller a country's share of world publications in a field, the larger its relative citation ratio can be, based purely on statistics.

Text table 5-6. Citations in U.S. papers to papers from selected countries: 1977 and 1986

Cited country	Year of citing papers 1977	1986
	—— Percent ——	
United States	71.5	70.5
All foreign countries	28.5	29.5
France	2.1	2.6
Japan	2.1	3.5
United Kingdom	7.3	5.9
West Germany	2.8	3.4

Note: Cited papers are counted in a 2-year-lag, 3-year rolling cycle. For example, citing papers published in 1986 provide data on cited papers published in 1982-84.

See appendix table 5-33.

Science & Engineering Indicators—1989

approximately 35 percent of citations in foreign S/E papers must be to U.S. publications.

U.S. Cross-Sector Citations. The various U.S. employment sectors overcite their own S/E literature in the same way that individual countries do;[60] they also usually undercite papers from other sectors, albeit to varying extents.[61] (See appendix table 5-35.) With few exceptions, this overall pattern was generally stable between 1977 and 1986.[62]

University papers dominate the references in U.S. publications. Because the academic sector produces 70 percent of the U.S. S/E literature, this finding is not surprising. In 1986, more than half the citations to U.S. papers were to the U.S. academic sector, except when industry was the citing sector. However, even industry has cited more academic papers than industry papers since 1984. (See appendix table 5-35.)

Citations in Engineering/Technology Papers. As an indicator of the role of basic research in the development of technology, citations in engineering/technology journals were examined. Engineering/technology papers primarily cite their own field. In 1984, 67 percent of their references were to other engineering/technology papers; 16 percent of the references were to physics papers, and 9 percent to chemistry papers. (See appendix table 5-36.) These proportions have remained constant since 1976.

Further analysis focused on the distribution between applied research and basic research of the cited physics and chemistry papers and on the comparison of this cited distribution of papers with the world distribution.[63] (See appendix table 5-36.) Of the 25 percent of citations in engineering/technology papers to chemistry and physics papers, about a third of the cited chemistry and physics papers are in basic research journals and two-thirds in applied research-targeted basic research journals. However, this citation distribution by type of research is the reverse of the world distribution of papers in these two fields. Thus, engineering/technology papers show some attention to basic research in chemistry and physics, but preferential attention to applied research-targeted basic research in those fields.

Patents Awarded to Universities

University patenting has increased during the 1980s,[64] due in part to the 1980 change in the U.S. patent law that allows universities and small businesses to retain title to inventions resulting from research funded by the Federal Government. U.S. universities received 2.0 percent of patents awarded to U.S. inventors in 1988, more than double their 0.9-percent share in 1978.[65]

Patent Classes. Universities concentrate their patenting in relatively few patent classes, many of which are in biomedical areas. Of the 404 patent classes of the U.S. Patent and Trademark Office, only 21 patent classes accounted for more than half of the 7,798 patents awarded to U.S. universities between 1971 and 1988. (See appendix table 5-37.) In 1988, universities patented most prolifically in four biomedical patent classes: these four classes represented 32 percent of university patents, compared with 5 percent of all patents awarded to U.S. inventors. (See text table 5-7.)

Characteristics of the Highest Patenting U.S. Universities. Nine of the ten U.S. universities with the largest numbers of patents in 1988 heavily patent in biomedical

[60]Unpublished data from Computer Horizons, Inc., show that individual foreign countries overcite papers from their own country; this effect is most severe for papers published nearest to the publication year of the citing paper.

[61]Only papers with U.S. authors are counted as cited or citing papers in this section. Both cited and citing papers are counted as appropriate fractional papers when there are authors from more than one country or more than one sector. See footnote 50 for an explanation of assignment of fractional papers.

[62]Because of year-to-year variability in relative citation ratios, apparent time trends should be interpreted cautiously.

[63]The analysis used a four-level categorization system for S/E journals, developed by Computer Horizons, Inc. The categories ranged from the most applied technology to the most basic science.

The world distribution of papers by research category and field was provided by Computer Horizons, Inc., for 1973 to 1979. Because the proportions were constant during those years and consistent with later data, the 1973-79 distributions have been used.

[64]U.S. Patent and Trademark Office (1989).

[65]The minimum percentage of U.S.-invented university patents awarded to women was 1.8 percent in 1975, 2.5 percent in 1981, and 5.1 percent in 1987. In this last year, at least 36 women from U.S. universities were awarded patents. The percentage of *total* U.S.-invented patents awarded to women was at least 1.6 percent in 1975 and 2.9 percent in 1987.

The percentages for women are minimum figures since gender-ambiguous names could not be assigned. Because the number of unidentified and gender-ambiguous names exceeds the number of identified women, the percentage of women patent-holders could be considerably higher than the minimum figures presented here. CHI provided these unpublished data, based on the 100 top patenting universities in the United States, which account for over 90 percent of university patents. Gender was assigned based on names.

Text table 5-7. Most active patent classes for academic sector patenting: 1988

Patent class and name	Patents to academic institutions	Patents to U.S. inventors	Academic share of patents
	Number		—Percent—
Total, all classes	801	40,496	2.0
Total, these four classes	257	2,156	11.9
435 Chemistry: molecular biology and microbiology	91	441	20.6
514 Drug, bioaffecting and body treating compositions	80	823	9.7
128 Surgery	47	901	5.2
424 Drug, bioaffecting and body treating compositions	39	432	9.0

See appendix table 5-37 and chapter 6.

Science & Engineering Indicators—1989

areas, mirroring the pattern for all universities combined.[66] (See appendix table 5-38.) The sole exception, Caltech, gets small numbers of patents in a great variety of patent classes. These top 10 universities received 38 percent of the patents awarded to universities in 1986-88, a disproportionately large share. This distribution pattern also occurs with other indicators of university R&D; for example, these 10 universities receive a relatively large share of academic R&D funding. (See appendix table 5-6.) Furthermore, many of these top patenting universities also rank in the top 10 in numbers of publications in various fields.

[66]Numbers of patents in 1988 for the year's top 10 patenting universities are: MIT, 63; University of California, 59; Stanford University, 54; University of Minnesota, 26; Johns Hopkins University and the University of Florida, 21 each; University of Wisconsin, 20; Caltech and the University of Texas, 18 each; and Harvard University, 17.

Dependence of Manufacturing Industries on Academic Research

Various efforts have been made to quantify the role that academic research plays in industrial development of new products. In the first empirical attempt to estimate the economic return to society from this research, Mansfield (forthcoming, 1990) found that industry depends heavily on recent academic research. (See text table 5-8.) A very rough estimate of the minimum annual social rate of return from the academic research discussed in this study was 28 percent.

Mansfield's results were based on a probability sample study of 76 major American firms in 7 manufacturing industries. Executives were asked about new products and processes they had introduced between 1975 and 1985. They said that a substantial proportion of these new products and processes depended on academic R&D, in that they either:

- Could not have been developed (without substantial delay) in the absence of recent academic research, or
- Were developed with very substantial aid from recent academic research.

The drug industry showed the greatest dependence on academic research, with 44 percent of its new products depending on such research.

Text table 5-8. Percentage of new products and processes based on recent academic research for seven U.S. industries: 1975-85

Industry	Percentage whose development depended on recent academic research[1]: Products	Processes
Information processing	28	27
Electrical	9	7
Chemical	8	6
Instruments	21	3
Drugs	44	37
Metals	22	21
Oil	2	2

[1]Percentage that either could not have been developed (without substantial delay) in the absence of recent academic research or that were developed with very substantial aid from recent academic research.

SOURCE: Mansfield (forthcoming, 1990).

Chapter 6
Industrial R&D and Technology

CONTENTS

Industrial R&D and Technology

HIGHLIGHTS

- *Expenditures for industrial research and development (R&D) are growing, but this growth is beginning to slow.* Total industrial expenditures for R&D are estimated at $95.4 billion in 1989; this is 72 percent of all R&D expenditures in the United States. From 1980 to 1985, the average annual increase in industrial R&D performance was 6.3 percent in constant dollars. However, increases averaging only 1.8 percent per year are estimated from 1985 to 1989. (See pp. 129-31.)

- *Private industry has funded more than one-half of all industrial R&D every year since 1968, and since 1979 has funded about two-thirds of the total.* From 1980 to 1985, company funding increased by an average of 5.4-percent per year in constant dollars. There was essentially no growth from 1985 to 1986. From 1986 to 1989, estimates are that company funding went up by only 2.3 percent per year. (See pp. 129-31.)

- *The rate of increase of Federal funds for industrial R&D is slowing after a period of rapid growth.* From 1980 to 1985, Federal funds for industrial R&D increased at a rate of 8.1 percent per year in constant dollars. The growth from 1985 to 1986 was less than 1 percent. From 1986 to 1989, only a 2.1-percent annual increase is estimated. (See pp. 129-31.)

- *Between 1980 and 1986, R&D expenditures increased especially rapidly in high-tech manufacturing industries.* The growth rate was 5.8 percent per year in constant dollars. In other manufacturing, growth was 4.4 percent per year; in nonmanufacturing, it was 2.0 percent per year. Growth was especially rapid in chemicals and allied products and in electrical equipment. (See p.131.)

- *The Federal Government supports an especially high share of industrial R&D in defense-related industries, such as aircraft and missiles (74.5 percent Federal) and electrical equipment (42 percent Federal).* From 1980 to 1986, Federal support grew especially rapidly—by 9.6 percent per year in constant dollars—in the communication equipment industry. In machinery, including computers, the growth of Federal funding was 9.2 percent per year. These industries are also highly defense-related. (See p. 131.)

- *The number of U.S. patents granted to Americans has reversed its decline and has been increasing since 1983.* After a decline averaging 2.1 percent per year from 1969 to 1983, in terms of date of patent application, there was a 5.4-percent per year increase from 1983 to 1988. However, foreign patenting increased by 9.1 percent per year from 1983 to 1988. (See pp. 132-33.)

- *The share of U.S. patents granted to foreigners rose to 48 percent in 1988.* The Japanese share was 21 percent, and is still growing rapidly; it was 10 percent in 1978. (See pp. 132, 135, 139.)

- *Japanese patenting in the United States emphasizes certain specific technology fields that are commercially important, such as photocopying, information storage and retrieval, photography, motor vehicles, and typewriting machines.* American inventors give especially low emphasis to those fields, but do emphasize chemical fields like biochemistry, petroleum, and pharmaceuticals. (See pp. 136-38.)

- *The share of U.S. patents going to U.S. nationals declined in most broad industries from 1978 to 1988.* The share granted to Americans fell from 64 to 44 percent in office, computing, and accounting machines (including computers); and from 63 to 43 percent in motor vehicles. The Japanese share has grown in all broad industries, particularly in office, computing, and accounting machines. (See p. 139.)

- *Citations from U.S. patents to earlier U.S. patents suggest that the patents received by Japanese and U.S. corporations are most frequently cited and therefore may be of especially high quality.* Patents granted to inventors from other countries and those owned by U.S. individuals or the U.S. Government are less frequently cited. (See pp. 139-41.)

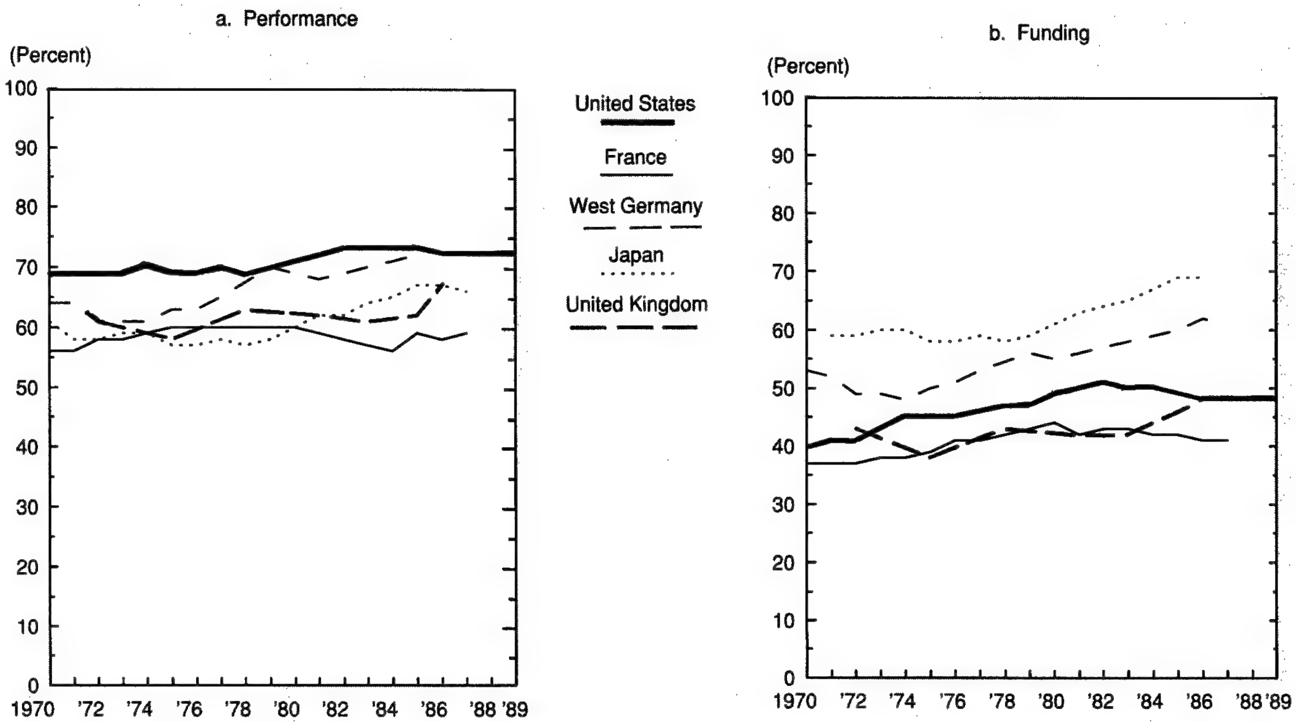
- *Small business establishments operating in high-technology fields prospered substantially more than those operating in other fields during 1980-86.* Employment in small business establishments operating in high-tech fields grew at more than double the rate of small business establishments in the entire U.S. economy. Employment in technology-related industries grew by 28 percent during this period, while employment in all small businesses grew by 11 percent. (See pp. 142-43.)

- *Small high-tech establishments exhibited a stronger tendency to leave the small business category through growth or mergers than did small non-high-tech establishments.* Also, small high-tech manufacturing establishments were more likely to grow or merge out of the small business category than were small business establishments performing high-technology services. Manufacturing businesses that operated in the communication equipment and electronic components industries were most likely to make the transition. (See p. 143.)

- *The pool of capital managed by venture capital firms grew dramatically during 1978-87.* Venture capital is an important source of funds used in the formation and expansion of small high-tech companies. In 1987, the pool of capital was eight times as large as it was in 1978. Pension funds were a growing source of new money committed to venture capital firms. (See pp. 144-45.)

• *Small businesses continue to play an important role in the biotechnology industry, accounting for 95 percent of all firms operating in the field during 1988.* There are indications that the industry's rapid growth during the early 1980s may be slowing down. Since 1985, there has been a steady decline in new biotech firms. During 1987, capital raised through initial public offerings for biotechnology firms declined by 50 percent compared with that raised during 1986. (See p. 145.)

Figure 6-1.
Industry funding and performance of R&D, as a percentage of total R&D, in selected countries



See appendix table 6-1.

Science & Engineering Indicators—1989

Industry is, in many respects, the most important sector in any analysis of science and technology (S&T). In the United States, 72 percent of all research and development (R&D) expenditures are for R&D performed in industry. (See figure 6-1a.) Among other large industrialized market-economy countries, West Germany has a similar share of R&D *performed* by industry. Japan and the United Kingdom have somewhat lower shares (66 or 67 percent), while in France about 59 percent of national R&D expenditure is in industry. The share of R&D performed in industry has actually increased in West Germany (since the early 1970s) and in Japan (since the middle 1970s).

Private industry is the *source* of 48 percent of all funds spent for R&D in the United States,[1] with the rest provided by the Federal Government. Nearly all industry funding is for R&D that will be performed in industry itself.[2] Of the other four countries shown on figure 6-1b, Japan and West

[1]This number actually includes funding from all non-Federal sources, including state and local governments, but nearly all of this is in fact private funding.

[2]About 1 percent is spent on university research, and almost 1 percent on research in nonprofit institutions. For a discussion of industry support for R&D in colleges and universities, see chapter 5.

Germany have a considerably larger share of their national R&D funds coming from private sources than the United States has. France and—until recently—Britain have less of their R&D funded by industrial sources.[3] In all five countries, the trend since the early 1970s seems to be for increased shares of industrial support of R&D. In the United States, however, the trend has reversed slightly, with lower shares of private support since the peak year in 1982. This is due primarily to the buildup of Federal R&D for defense in the 1980s.

This chapter discusses private and Federal funding of R&D in U.S. industry. Industrial R&D is the principal source of technological developments that benefit the entire economy. Some of these benefits are seen in the production of new technical inventions. These are discussed in terms of the patents granted to Americans and also to foreign inventors. Another aspect of industrial technology is the formation and growth of high-tech small companies; these are the subject of the last section of this chapter. U.S. industry's experience in the international marketplace for high-tech products is discussed in chapter 7. The employment of scientists and engineers in industry is treated in chapter 3.

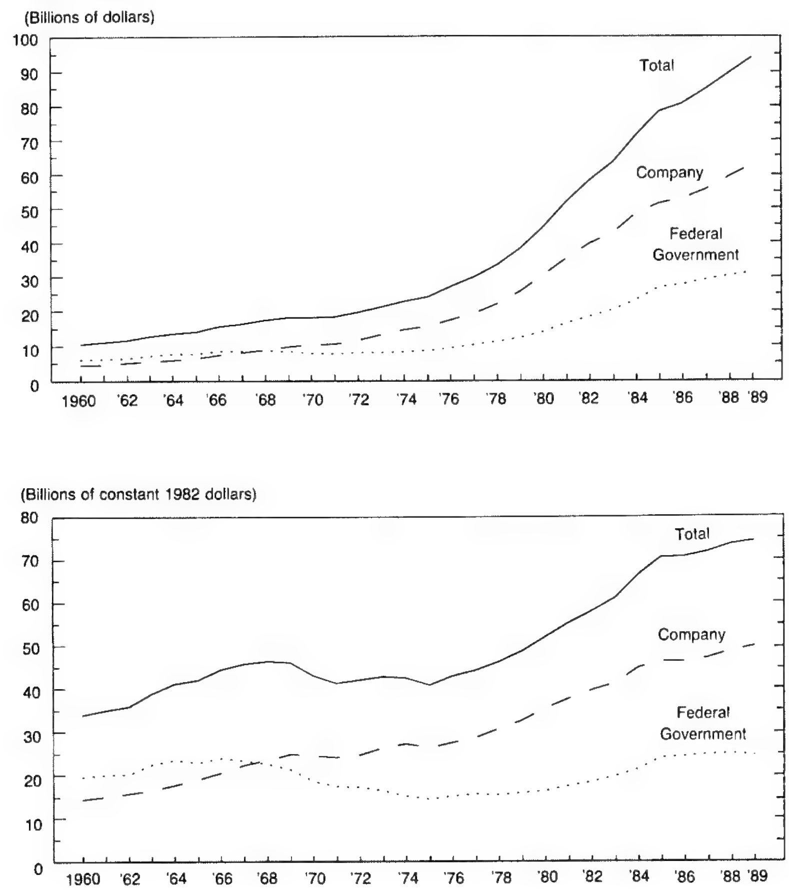
[3]For France and Britain, the data shown include R&D funding provided by public, as well as private, corporations. Thus, the level of private funding for industrial R&D is lower than is shown on figure 6-1.

EXPENDITURES FOR RESEARCH AND DEVELOPMENT IN U.S. INDUSTRY

Trends in constant-dollar funds spent on industrial R&D are indicators of the level of R&D activity in U.S. industry. Funds for industrial R&D come almost exclusively from two sources: private industry itself and the Federal Government.[4] Total current-dollar expenditures for industrial R&D have increased markedly in the 1980s, with $90.6 billion estimated for 1988 and $95.4 billion estimated for 1989. (See figure 6-2.) This increase repre-

[4]Some companies perform independent research and development (IR&D), i.e., in-house R&D intended to better prepare the companies to bid on National Aeronautics and Space Administration or Department of Defense projects. Some of these expenditures are later reimbursed by the agency as overhead charges allocated to contracts. In this chapter, IR&D expenditures are counted as company-funded R&D.

Figure 6-2.
Expenditures for industrial R&D, by source of funds



See appendix table 6-2.

Science & Engineering Indicators—1989

sents an 8.8-percent annual growth rate from 1980 to 1989 in current dollars. In constant-dollar terms, total R&D funding in industry has risen every year from 1975 to 1989. From 1980 to 1985, the growth rate was 6.3 percent per year. This rate has slowed in recent years, however: it was only 0.9 percent per year from 1985 to 1987. An increase of only 2.9 percent is estimated from 1987 to 1988, and only 1.3 percent from 1988 to 1989.

Trends in Company and Federal Funding

The share of industrial R&D funding coming from the companies themselves increased steadily from the early 1960s until 1980. (See figure 6-2 and appendix table 6-2.) From 1980 until 1986, this trend was reversed as the military buildup led the Federal contribution to increase more rapidly than the private contribution. Since 1986, preliminary data and estimates suggest that the trend has begun to return to the older pattern, with private financing increasing a little more rapidly than Federal financing.

More specifically, from 1963 until 1980, private funding for industrial R&D increased at an average rate of 4.6 percent per year (in constant dollars), while Federal support decreased by 1.8 percent per year. From 1980 to 1985, company support continued its increase at a rate of 5.4 percent per year, but Federal support went up by 8.1 percent per year on average. From 1985 to 1986, there was essentially zero growth in company-funded R&D, while Federal funding went up less than 1 percent.

After 1986, the overall growth in funding seems to have resumed, but at a slower rate than in the early 1980s. From 1986 to 1989, estimates are that company funding went up by only 2.3 percent per year, while Federal funding went up by 2.1 percent per year. Most of this Federal funding increase was from 1986 to 1987; after that, estimates are for sharply decreasing rates of Federal growth. As a result, company funds were 42 percent of all industrial R&D funding in 1963, 68 percent in 1980, 66 percent in 1986, and an estimated 66 percent in 1989.

The very slight increase in Federal support in the last few years is largely because of concern over the Federal budget deficit. In the case of private industry, the relatively low rate of increase of R&D funding has been attributed to (1) relatively small increases in sales and profits, (2) greater emphasis on cost reduction programs, and (3) closer ties between R&D and manufacturing operations, as well as (4) the increase in corporate mergers.[5] Other analyses indicate that mergers and acquisitions in expanding markets are accompanied by increases in R&D; in declining markets, reductions of R&D are more likely to result.

R&D Expenditures in Individual Industries

Individual industries show very different trends in both their R&D expenditures and in the sources of support of those expenditures. It is helpful to divide industries into three general groups: high-technology manufacturing, other manufacturing, and nonmanufacturing.[6] (See figure 6-3.)

High-tech manufacturing industries accounted for 74 percent of industrial R&D expenditures in 1986, up from 72 percent in 1980. Other manufacturing industries accounted for 23 percent. Nonmanufacturing (including services) accounted for only 3 percent. However, innovation in the service industries is sustained by R&D-based products introduced by manufacturing industries, as well as by R&D within those industries themselves. From 1980 to 1986—a period of economic slowdown followed by recovery—total industrial R&D rose by an average of 5.3 percent per year in constant dollars. During this time, R&D within the three industry groups increased as follows:

- High-tech manufacturing—5.8 percent per year,
- Other manufacturing—4.4 percent per year, and
- Nonmanufacturing—2.0 percent per year.

Growth was especially rapid in the high-tech manufacturing industries chemicals and allied products and electrical equipment. (See appendix table 6-3.)

Certain industries receive especially large portions of their R&D support from Federal sources. (See text table 6-1.) This is particularly true in aircraft and missiles and in electrical equipment, which are of special military importance. For example, electronics are an increasingly important component of air weapons systems. Nonmanufacturing industries as a group also have a large share of their R&D funding contributed by the Government. This is the only group to show a clear increase in the Government's share of R&D funding since 1980.

While total Federal support for industrial R&D increased at an average rate of 6.9 percent per year (in constant dollars) from 1980 to 1986, the increase was much more rapid in some industries. In particular, it was 9.6 percent per year in communication equipment, 9.2 percent per year in machinery (including computers), and 7.7 percent per year in all nonmanufacturing. (See appendix table 6-4.) On the other hand, Federal funding of chemical industry R&D declined by 10.8 percent per year.

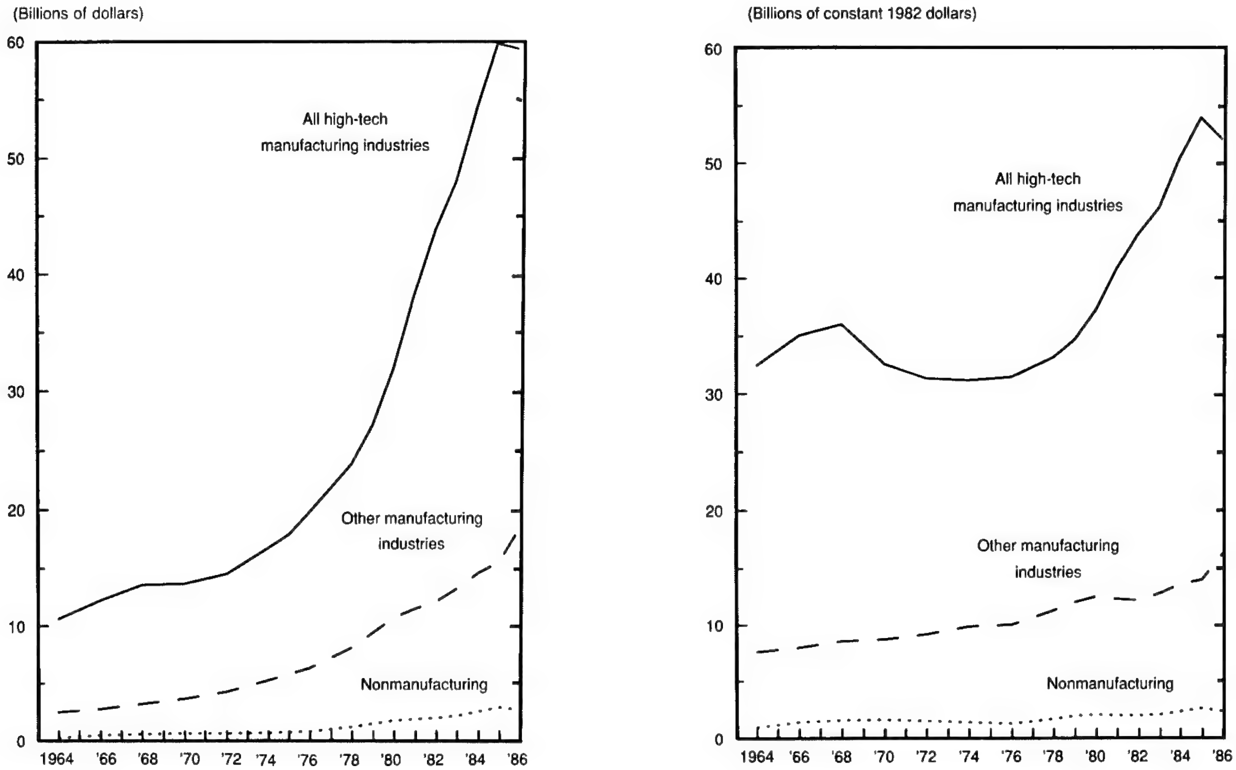
Company funding for industrial R&D increased by 4.5 percent per year from 1980 to 1986 in constant dollars. (See appendix table 6-5.) The fastest increases were in chemicals and allied products (7.6 percent per year) and in electrical equipment (6.4 percent per year).

Company funding in high-tech manufacturing industries went up 5.8 percent per year, while it went up 2.5

[5]See NSF (1988a) and (1989).

[6]A list of manufacturing industries in the two groups is shown in appendix table 6-3, along with trends in R&D expenditures in each industry. High-tech industries are identified in terms of the ratio of their R&D expenditures to their net sales. The nonmanufacturing industry group here comprises agriculture, forestry, and fishing; mining and construction; transportation, communications, electric, gas, and sanitary services; wholesale and retail trade; finance, insurance, and real estate; computer and data processing services; research and development laboratories and other miscellaneous business services; medical and dental laboratories; and engineering, architectural, and surveying services. Of course, only some of these report significant R&D expenditures. In the future, it will be possible to report R&D expenditures for some specific nonmanufacturing industries. Throughout this chapter, the 1972 Standard Industrial Classification (SIC) is used.

Figure 6-3.
Research and development expenditures, by industry group



See appendix table 6-3.

Science & Engineering Indicators—1989

percent per year in non-high-tech manufacturing and actually declined 3.7 percent per year in nonmanufacturing. This is a major departure from the trend in Federal funding. Federal support grew by 5.7 percent, 15.0 percent, and 7.7 percent per year, respectively.

From 1986 to 1988, quite different trends are estimated for company funding. (See appendix table 6-5.) While high-tech manufacturing industries are expected to have maintained a growth rate of 5.0 percent per year in constant-dollar R&D expenditures, a net decline is expected in all other industries combined. Chemicals and allied products and electrical equipment are not expected to have maintained nearly the growth rates of recent years, while machinery (including computers) is expected to have had a very high growth rate of 12 percent per year.

PATENTED INVENTIONS

Industrial R&D produces many benefits for the performing company. One of the main benefits is a stream of new technical inventions that may in turn be embodied in innovations—i.e., in new or improved products, processes, and services. As a measure of the success of U.S. industry in producing new inventions, it would be desirable to be able to count them and show their trend over time. While there is no accepted method for counting inventions as such, the *patents* taken out for inventions can provide an indicator of the rate of invention.[7]

Inventors and Owners of Inventions Patented in the United States

Patents by Date of Grant—General Trends. The U.S. Patent and Trademark Office issues patents to both U.S. and foreign inventors. This discussion is limited to patents actually *granted*, rather than to those only *applied for*; furthermore, it deals only with patents granted by the *U.S.* patent office. In 1988, U.S. inventors received 52 percent of U.S. patents granted, while foreigners received the remaining 48 percent. (See figure 6-4 and appendix table

[7]Patenting indicators, while instructive and convenient, have some well-known drawbacks. For one thing, many inventions are not patented. This is due in part to laws in different states that provide for the protection of industrial trade secrets. Different industries vary considerably in their propensity to patent their inventions, so that it is not advisable to compare patenting rates across different technologies or industries. In addition, there are various reasons for applying for patent protection, and the inventions patented can vary considerably in quality. (One method of dealing with the question of varying quality, based on patent citations, is discussed later in this section.) These limitations should be kept in mind when using patent counts to represent levels of invention. Nevertheless, patents provide a unique source of information on this subject.

Text table 6-1. Share of R&D funding provided by the Federal Government in selected industries: 1980-86

Industry	1980	1983	1984	1985	1986 (prel.)
	Percent				
Total	31.5	32.4	32.4	34.3	34.5
Chemicals and allied products (SIC 28)	8.0	6.1	2.9	3.4	2.7
Industrial chemicals (SIC 281-2, 286)	15.5	12.9	6.3	7.2	6.1

Science & Engineering Indicators—1989

6-6.) This is the highest share of U.S. patents that foreigners have ever received.[8]

The peak year for patents granted to Americans was 1971.[9] Patenting declined from that year to 1982 and 1983—i.e., shortly after the 1980-81 recession—and has been increasing fairly rapidly since that time.[10] By 1987, U.S. patenting had again reached the level of the mid-1970s, having increased by 7.3 percent per year from the 1983 low. Foreign patenting in the United States was also experiencing a slight dip in 1983. From 1983 to 1987, it rose at a rate nearly twice that of U.S. domestic patenting—13.2 percent per year.[11]

[8]A few of these foreign inventors actually work for U.S. concerns. In 1988, 6 percent of the patents granted to foreigners had U.S. corporations registered as their owners. In 1978, this proportion was 8 percent.

[9]This is the peak year for patents classified by date of grant. Granted patents can also be classified by date of application, as discussed in the section "Granted Patents by Date of Application," p. 136.

[10]There is a dip in the number of patents granted to all countries in 1979. This is because the patent office budget was insufficient to print all the patents approved in that year.

[11]Both U.S. and foreign patenting declined from 1987 to 1988. This is one of many oscillations that appear in patenting data by year of patent grant. It reflects the especially low number of patents that were awarded in 1986 because of budget restrictions at the patent office. This in turn led to a carryover of patents into 1987, and, consequently, an unusually high number of patent grants in that year. The discussion of "Granted Patents by Date of Application" (p. 136) shows that there was no real decline in U.S. and foreign patenting activity from 1987 to 1988.

Interpretations of Trends. These trends are open to various interpretations.

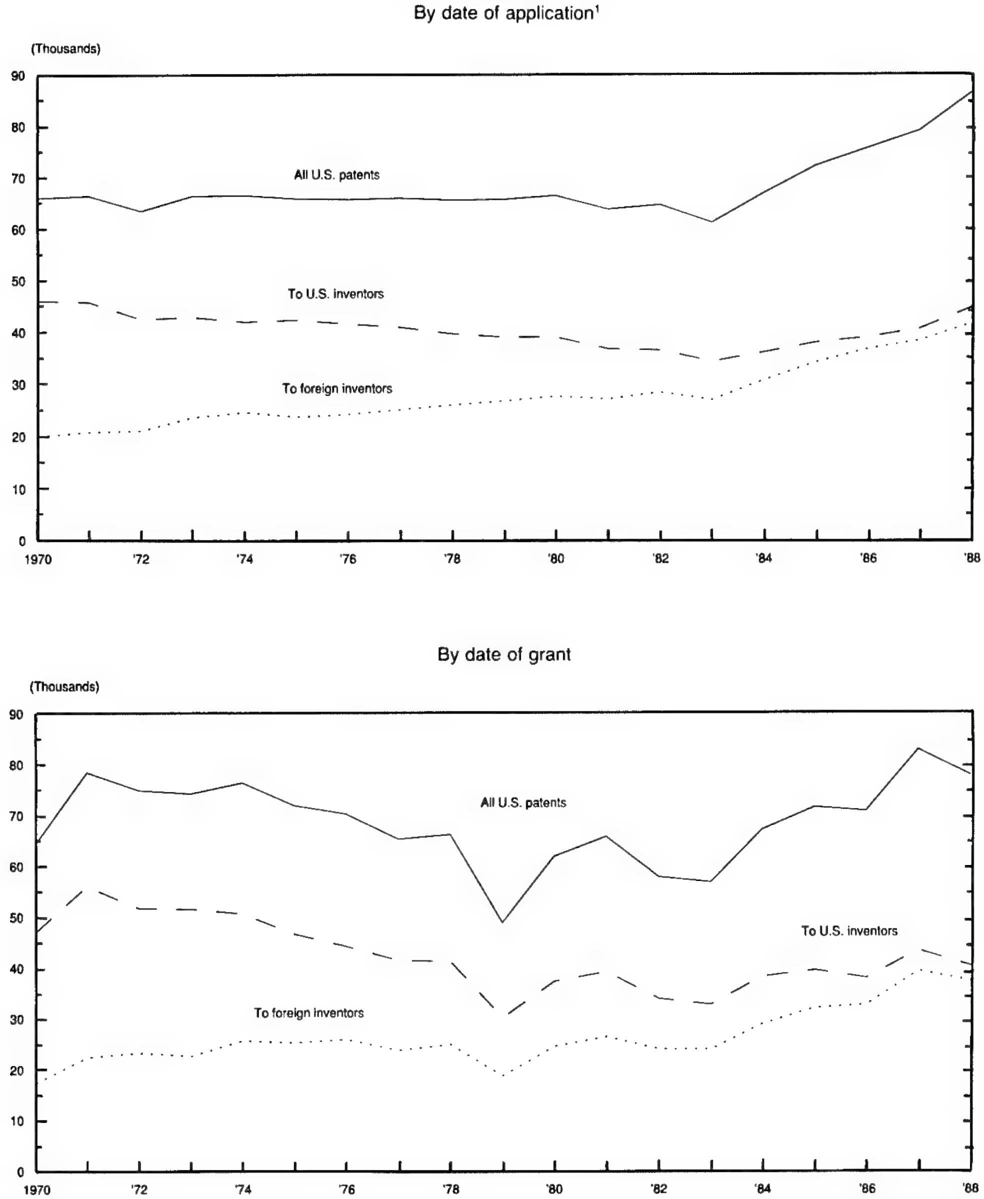
- If a country's domestic patenting is taken as an indicator of its production of inventions, then the production of inventions in the United States declined in the 1970s and has been increasing since 1983.[12] In this view, increases in patenting in the United States by foreign countries may be attributed to the desire to exploit the U.S. market, and not to any increase in inventions by those countries.

- On the other hand, patenting by foreign countries in a large country like the United States may be considered an indicator of the levels of invention in those foreign countries. Under this assumption, the rapid increase of foreign patents in the United States since 1983 suggests a rapid increase in foreign levels of invention.[13]

[12]Many other industrialized countries, excluding Japan, had similar declines in domestic patenting.

[13]These two interpretations are illustrated by Schiffel and Kitti (1978) and by Pavitt (1985). Data from the *European* Patent Office show that the Japanese share of patents rose from 7.5 percent to 13.0 percent in the short interval from 1983 to 1985. The share of patents granted to Americans remained virtually constant at 22.7 percent. In the same interval, the number of patents granted by the *Japanese* patent office to Americans and to citizens of the contracting states of the European Patent Office was

Figure 6-4.
U.S. patents granted, by nationality of inventor



[1]Estimates are shown for 1981 to 1988 for patents by date of application.
See appendix table 6-6.

Science & Engineering Indicators—1989

It is possible, of course, that some foreign countries (e.g., Japan) may have both an increasing number of inventions *and* a growing interest in patenting in the United States.

Further, the costs of acquiring a U.S. patent are often higher for a foreign filer than for an American. Thus, foreign patents may represent a more selective set of inventions—for example, those owned by multinational corporations and aimed at U.S. markets as part of a company's global strategy. Such patenting is especially responsive to economic and market influences. The increase in foreign patenting in the United States is thus part of the general internationalization of the U.S. economy. In any case, one consequence of the trends discussed here is that more and more of the new technologies available for commercial exploitation in the United States are owned and controlled by foreign corporations.

nearly identical: both lost a small part of their share, dropping from about 8.2 to 7.3 percent. See U.S. Patent and Trademark Office (1985a), pp. 3 and 41. Thus, Japanese inventors are the only group of the three to show an increasing share of patents in all three patent offices.

Recent research has emphasized also that the trends in the *numbers* of patents are not necessarily the same as the trends in their *quality*. For example, while the number of patents in the United Kingdom, France, and West Germany began to decline in the mid- or late 1960s, the average quality of the patents increased, with the result that the total value of patent rights actually increased.[14] This is related to the finding that a small portion of all patents has most of the total value. Further research is extending these results to more countries and various fields of technology.

Patents Granted to Americans, by Sector. Patents granted to American inventors can be further analyzed according to who owns them. Inventors who work for private companies or for the Government commonly assign ownership of their patents to their employer; self-employed inventors usually retain ownership of their patents. The owner's sector is thus a good indication of the sector in which the inventive work was done. In 1988, 72 percent of patents granted to Americans were owned by *U.S. corporations*.[15] This percentage has varied within a narrow range, i.e., from 74 in 1970 to 70 in 1980. Thus, trends in U.S. patenting are largely trends in patenting by corporations. *U.S. individuals* are the next largest group of owners of patents granted to Americans, and their share has increased somewhat over the past two decades. It began at a relatively low level in 1970 (21 percent), rose to 27 percent in 1980, and was 25 percent in 1988. The *Government's* share of patents has varied from a high of 4 percent in 1976 to a low of 2 percent in 1988.[16] Finally, about 1 percent of patents granted to American inventors are owned by *foreign corporations or governments*.

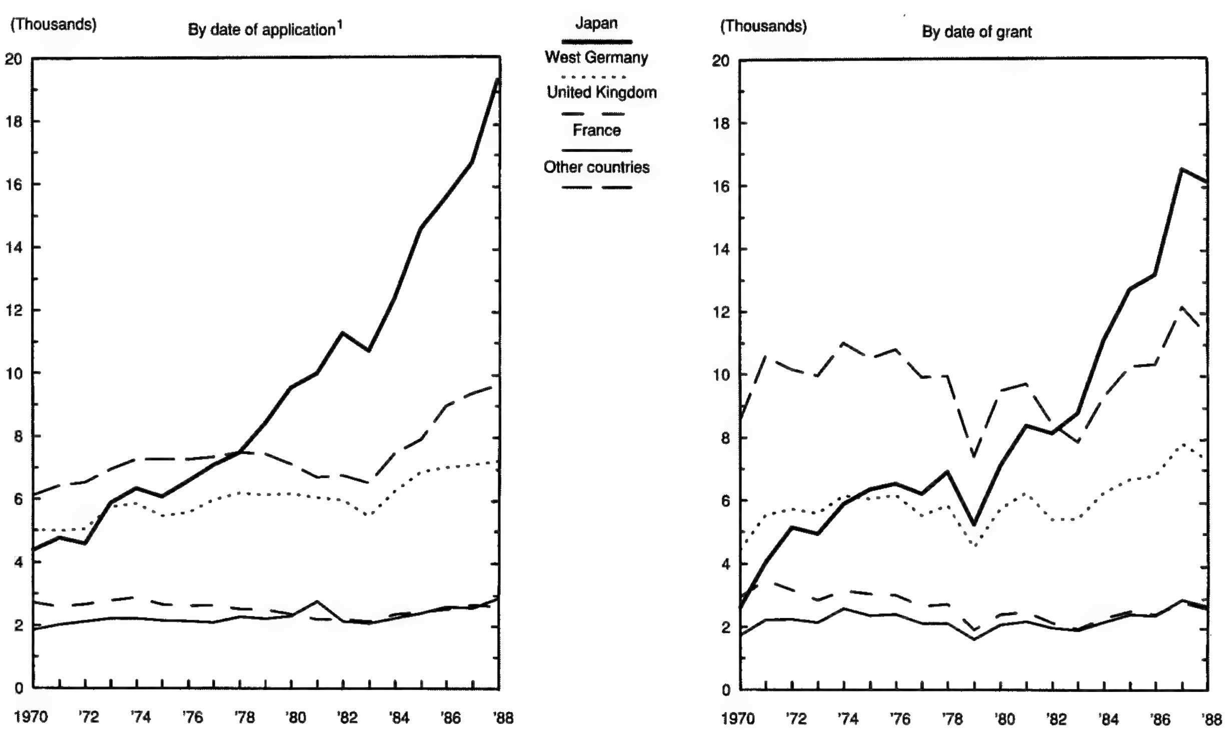
Patents Granted to Foreign Inventors, by Country. Foreign patenting is highly concentrated in terms of country of origin. (See figure 6-5.) Since 1975, Japan has received more patents than any other foreign country. Japanese inventors have steadily increased their share, receiving 21 percent of all U.S. patents in 1988. West Germany follows with 9 percent, while France and the United Kingdom are next with 3 percent each. Japanese patenting has had especially high growth; it has nearly doubled since 1983, for an annual growth rate of 12.9 percent. In the same

[14]Schankerman and Pakes (1986).

[15]About 2 percent of patents granted to Americans in 1988 were owned by U.S. universities and colleges. These are counted by the patent office as patents owned by corporations. For further discussion of academic patenting, see chapter 5.

[16]In addition to patents, the patent office sometimes awards Statutory Invention Registrations (SIRs), which are publications that are not ordinarily subject to examination and cost less to obtain than patents. They give the holder the right to use the invention and prevent others from patenting it, but do not keep others from selling or using the invention. Government inventors get the majority of SIRs. In 1988, they were awarded 728 patents and 114 SIRs.

Figure 6-5.
U.S. patents granted to foreign inventors, by nationality of inventor



[1]Estimates are shown for 1981 to 1988 for patents by date of application. See appendix table 6-6.

Science & Engineering Indicators—1989

1983-88 period, other countries' patenting has grown as follows:

- West Germany, 6.1 percent per year;
- France, 7.0 percent per year;
- United Kingdom, 6.0 percent per year; and (for comparison)
- The U.S., 4.3 percent per year.

Granted Patents by Date of Application. Patent data in terms of the year in which the patent was granted show considerable oscillation from year to year. (See figures 6-4 and 6-5.) Much of this is due to fluctuations in the rate at which the patent office processes applications, rather than to any fluctuation in the filing of applications by inventors. To remove the effect of fluctuations in processing rates, granted patents can be allocated to the years in which they were applied for. The application date is roughly 2 or 3 years before the year of grant, and is closer to the time at which the invention actually took place.

By year of application, patenting data show much smoother trends. (See figures 6-4 and 6-5.)[17] In these terms, from the batch of applications filed in 1988, 48 percent of the U.S. patents that will be granted will go to foreign inventors. Japan will receive 22 percent, the West German share will drop to 8 percent, and France and the U.K. will—again—have 3 percent each.

In terms of application date, patents granted to U.S. inventors decreased fairly regularly from 1969 to 1983 at an annual average rate of 2.1 percent. They have increased steadily since the low point in 1983[18] at an average rate of 5.4 percent per year. From 1987 to 1988 alone, they rose by 10 percent, and have again reached the level of the early 1970s.

Japanese patenting has grown by 12.5 percent per year over this period, with a 16-percent increase from 1987 to 1988. Since 1970, annual Japanese patenting in the United States has increased by a factor of 4.4. West Germany's patenting in the United States has increased by 5.7 percent per year from 1983 to 1988, in terms of application date. For France, the increase was 6.7 percent per year, while for the United Kingdom it was 3.9 percent per year. Overall, France has had a substantial increase in its U.S. patenting since 1970, and has overtaken the United Kingdom. (See appendix table 6-6.) These results show that Japan is maintaining the fastest growing rate of filing applications in the U.S. patent office,[19] and will continue in the immediate future to increase its share of patents.

Patent Fields Favored by Inventors From Different Countries

Patent counts give an idea of the amount of inventive activity and output by different countries, but it is also important to know how an individual country's patents are distributed among specific *technical areas*. A large number of patents held by a given country is more meaningful if those patents are in important fields of technology. The best classification system to use in looking at individual fields of patenting is the one that divides patents into the narrowest and most specific classes. This is the U.S. Patent and Trademark Office's own classification system, which contains approximately 370 active classes pertaining to inventions. The patents received by U.S. and foreign inventors in recent years can be compared in terms of these classes.[20]

Comparison of Fields Favored by U.S. and Japanese Inventors. Because of the special interest of U.S.-Japanese comparisons, text tables 6-2 and 6-3 show the areas of greatest and least concentration by American and Japanese inventors patenting in the United States.[21] More extensive data are given in appendix tables 6-7 and 6-8. Comparable data on West German, French, and British patenting in the United States are given in appendix tables 6-9, 6-10, and 6-11. Together, these five countries account for 89 percent of all patents granted in the United States.

To some extent, there is an inverse relationship between U.S. and Japanese patenting. (See text tables 6-2 and 6-3.)[22]

[17]Since many of the patent applications filed in recent years have not yet been examined by the patent office, it is not known how many of these will ultimately become granted patents. The expected number of granted patents for recent application years can be estimated by multiplying the total number of applications for any year by the recent success rate. Such estimates are used for patenting rates by date of application throughout this chapter.

[18]The data series for patent grants by date of application shows a dip in 1983 for many countries. In fact, the number of applications from many countries was especially high in 1982 and correspondingly low in 1983. This is largely because a new schedule of higher fees was introduced in late 1982, leading to an acceleration of filings in 1982 and fewer in 1983.

[19]Japanese applications also lead to grants more often than do applications from any of the other countries discussed here. For example, an estimated 68.3 percent of the patent applications filed by Japanese inventors in 1985 will lead to patent grants. The percentages for other countries are France, 66.7 percent; West Germany, 65.9 percent; and United States, 59.5 percent.

[20]An earlier report comparing the fields emphasized by U.S. and Japanese inventors in their U.S. patents is Narin and Olivastro (1986). See also Narin and Frame (1989).

[21]The listing is limited to the 130 patent classes that received at least 200 patents, from all countries, in 1988. Thus small fields are not considered. The fields are ordered in terms of the "activity index," which reflects a country's share of the patents granted in a field in 1988. The listings thus show the fields in which a country has high or low *shares* of the patents, rather than the fields in which it simply has high or low absolute *numbers* of patents. Note that "emphasis," as shown on these tables, is a relative term. For example, U.S. inventors "emphasize" certain fields only by comparison with foreign inventors, not by themselves.

[22]Since the United States is the host country, patents granted to American inventors have some special characteristics. In particular, most of the inventors who patent in the U.S. patent office but have no corporate or government affiliation are Americans. Unaffiliated foreign inventors are not likely to apply for American patents because of the difficulty and cost, and because they have little interest in patent protection in the United States. As a result, the data on patenting by Americans reflect a relatively large share of patenting by unaffiliated individuals and a relatively small share of corporate-affiliated patenting. (For example, 73 percent of U.S. patents granted to Americans go to inventors affiliated with corporations, while 96 percent of U.S. patents going to Japanese inventors are owned by corporations.) Unaffiliated individuals tend to patent in fields of little interest to industry, such as fishing, trapping, and vermin destroying, or

Text table 6-2. Patent classes most and least emphasized by U.S. corporations patenting in the United States: 1988

Most emphasized classes	Least emphasized classes
1. Mineral oils: processes and products	1. Fishing, trapping, and vermin destroying
2. Wells	2. Motor vehicles
3. Chemistry: analytical and immunological testing	3. Amusement devices, games
4. Chemistry: molecular biology and microbiology	4. Dynamic information storage or retrieval
5. Catalyst, solid sorbent, or support therefor, product or process of making	5. Photography
6. Error detection/correction and fault detection/recovery	6. Internal combustion engines
7. Semiconductor device manufacturing: process	7. Land vehicles
8. Part of the class 520 series—synthetic resins or natural rubbers	8. Ships
9. Glass manufacturing	9. Amusement and exercising devices
10. Electrical connectors	10. Dynamic magnetic information storage or retrieval
11. Amplifiers	11. Typewriting machines
12. Pulse or digital communications	12. Winding and reeling
13. Multiplex communications	13. Machine elements and mechanisms
14. Surgery	14. Geometrical instruments
15. Electrical computers and data processing systems	15. Photocopying
16. Part of the class 520 series—synthetic resins or natural rubbers	16. Tools
17. Drug, bioaffecting and body treating compositions	17. Chairs and seats
18. Food or edible material: processes, compositions, and products	18. Dentistry
19. Part of the class 520 series—synthetic resins or natural rubbers	19. Radiation imagery chemistry—process, composition, or product
20. Compositions	20. Plastic article or earthenware shaping or treating: apparatus

Note: Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988. Classes are listed in terms of the share of patents in each class that are awarded to U.S. inventors and owned by U.S. corporations, beginning with the class in which U.S. corporations have the greatest, or smallest, share.

See appendix table 6-7.

Science & Engineering Indicators—1989

For example, the Japanese get much more than their share of patents in such technically and commercially important technologies as photocopying, dynamic information storage and retrieval, dynamic magnetic information storage and retrieval, photography, radiation imagery chemistry, typewriting machines, motor vehicles, internal combustion engines, and machine elements and mechanisms. All of these are on the list of technologies in which American corporate inventors get much *less* than their share; this fact is clearly related to the Japanese penetration of U.S. markets in many of these areas.

The inverse relationship between Japanese and U.S. corporate patenting can be partly explained by the fact that in some fields the Japanese get such a large share of the patents that little is left for U.S. corporations and they must necessarily get a small share. Thus, it is important to ask whether there is further evidence that U.S. corporations are weak in these fields. For example, if Japanese patents were eliminated, would U.S. corporations still get low numbers of patents in these areas?

In photocopying, radiation imagery chemistry, and dynamic magnetic information storage and retrieval—all of which are on the list of fields with high Japanese emphasis and low U.S. corporate emphasis—U.S. corporations get more than their share of the non-Japanese patents.[23] Thus, the U.S. corporations show some strength in these areas, though the Japanese show more. On the other hand, in motor vehicles, internal combustion engines, and machine elements and mechanisms (which are also on this list), U.S. corporations did *not* receive their share of the non-Japanese patents.[24] These would appear to be definite areas of weakness for U.S. corporations. In dynamic information storage and retrieval, photography, and typewriting machines, U.S. corporations received about their share of non-Japanese patents. In these three fields, U.S. corpora-

amusement devices.

Therefore, to put the United States on the same basis as the other countries, text table 6-2 eliminates the patents owned by unaffiliated individuals and shows only patents granted to U.S. inventors affiliated with U.S. corporations.

[23]In 1988, U.S. corporations received 48 percent of all non-Japanese patents. But they received 76 percent of non-Japanese patents in photocopying, 61 percent of those in radiation imagery chemistry, and 60 percent of those in dynamic magnetic information storage and retrieval.

[24]In 1988, U.S. corporations received 26 percent of the non-Japanese patents in motor vehicles, 33 percent of those in internal combustion engines, and 40 percent of those in machine elements and mechanisms.

Text table 6-3. Patent classes most and least emphasized by Japanese inventors patenting in the United States: 1988

Most emphasized classes	Least emphasized classes
1. Photocopying	1. Aeronautics
2. Dynamic information storage or retrieval	2. Wells
3. Dynamic magnetic information storage or retrieval	3. Ammunition and explosives
4. Photography	4. Prothesis (i.e., artificial body members), parts thereof or aids and accessories therefor
5. Radiation imagery chemistry—process, composition, or product	5. Bottles and jars
6. Recorders	6. Amusement and exercising devices
7. Typewriting machines	7. Fishing, trapping, and vermin destroying
8. Static information storage and retrieval	8. Static structures, e.g., buildings
9. Pictorial communication; television	9. Surgery
10. Motor vehicles	10. Beds
11. Internal combustion engines	11. Geometrical instruments
12. Active solid-state devices, e.g., transistors, solid-state diodes	12. Tools
13. Machine elements and mechanisms	13. Hydraulic and earth engineering
14. Clutches and power-stop control	14. Stoves and furnaces
15. Electricity, motive power systems	15. Mineral oils: processes and products
16. Electrical generator or motor structure	16. Cleaning and liquid contact with solids
17. Registers	17. Special receptacle or package
18. Optics, systems and elements	18. Induced nuclear reaction, systems and elements
19. Stock material or miscellaneous articles	19. Receptacles
20. Metal treatment	20. Dispensing

Note: Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988. Classes are listed in terms of the share of patents going to Japanese inventors, beginning with the class most, or least, emphasized.

See appendix table 6-8.

Science & Engineering Indicators—1989

tions are at a disadvantage with respect to the Japanese, but not with respect to other foreign patenters.

While Japanese patenting in the United States emphasizes such areas as electronics, photography and photocopying, and motor vehicles, U.S. corporations emphasize patenting in chemical areas, including biochemistry, petroleum, and pharmaceuticals. (See text table 6-2 and appendix table 6-7.) Other areas of emphasis are communications and semiconductor manufacture. Wells and mineral oils—fields highly emphasized by Americans—are among those areas in which the Japanese patent the least, perhaps because of the lack of domestic oil production in Japan.

Over the 10-year period from 1978 to 1988, U.S. corporations have substantially increased their emphasis on molecular biology and microbiology (see appendix table 6-7); these fields are pertinent to the biotechnology industry. Other large increases were in communications, mineral oils, and glass manufacturing. On the other hand, large *decreases* occurred in U.S. relative activity in motor vehicles, dynamic information storage and retrieval, photography, typewriting machines, and photocopying. Not only are these technologies strongly emphasized by Japanese inventors and weakly emphasized by U.S. inventors, but also the U.S. emphasis in these areas has been decreasing in comparison with other countries. In a few of these areas—e.g., photocopying, typewriting machines, and motor vehicles—Japanese inventors have significantly increased their emphasis since 1978. (See appendix table 6-8.)

Fields Favored by Inventors in Other Countries. Data for West Germany, France, and the United Kingdom show each country's different technical emphases. For example, West Germany patents heavily in printing, in chemicals—including fertilizers and plastics—and in ammunition and explosives. (See appendix table 6-9.) There is low activity in photocopying, photography, and recorders (which are Japanese specialties), with an especially large drop from 1978 to 1988 in the German emphasis on photography. West German activity is also low in wells and mineral oils, which are areas emphasized by U.S. corporations.

French patenting emphasizes nuclear technology (which none of the other countries does) and communications, in addition to mechanical technologies like brakes and clutches. (See appendix table 6-10.) The French, like the Germans, also emphasize ammunition and explosives, which is among the least emphasized areas for the Japanese. Again like the Germans, the French do not get many patents in photocopying, an area of Japanese emphasis. Unlike the Germans, the French do not patent much in chemical fertilizers.

The British emphasize hydraulic and earth engineering and power plants. (See appendix table 6-11.) They share the American emphasis on drugs, glass manufacture, and

multiplex communications, as well as the French emphasis on aeronautics, which is the field least emphasized by the Japanese. The British, like the Germans and French, patent a great deal in brakes and organic compounds, but not much in photography.

Patenting in Various Industries by Inventors From Different Countries

Rather than using the U.S. patent office's classification system, patents can also be classified according to the Standard Industrial Classification, which allocates patents to the appropriate industries.[25] (See appendix table 6-12.) From 1978 to 1988, the share of U.S. patents going to American inventors dropped from 62 to 52 percent. Except for a slight increase in drugs and medicines, the U.S. share of patents dropped in all of the 16 SIC product fields shown. The drop was especially great in:

- Office, computing, and accounting machines—from 64 to 44 percent;
- Motor vehicles and other transportation equipment—from 63 to 43 percent;
- Communication equipment and electronic components—64 to 48 percent; and
- Aircraft and parts—54 to 41 percent.

In some of these cases, the falloff of U.S. share occurred because other countries were increasing their patenting more rapidly than the United States was. However, there was an actual drop in the total number of U.S. patents from 1978 to 1988 and—more specifically—in the number of U.S. patents in transportation equipment excluding aircraft and in aircraft and parts.

Japan's share of U.S. patents approximately doubled in this period, going from 10 to 21 percent of the total. The Japanese share increased in each of the 16 product fields shown, with an especially large share increase in office, computing, and accounting machines (rising from 15 to 40 percent). Japanese patenting in this field nearly reached the level of U.S. domestic patenting. Large increases in Japanese patenting also occurred in communication equipment and electronic components (from 14 to 30 percent), in textile mill products (from 11 to 26 percent), and in motor vehicles and other transportation equipment (from 11 to 26 percent).

The West German share of U.S. patents increased slightly from 1978 to 1988, with the greatest share increases in motor vehicles and other transportation equipment, aircraft and parts, and nonelectrical machinery. Decreases in share occurred in drugs and medicines and textile mill products. There were no substantial changes in the French shares of patents in various fields; however, there was a broad decline in the shares of patents going to the United Kingdom. The largest share declines for the United Kingdom were in drugs and medicines, textile mill products, and food and kindred products. Again, some of these decreases in share are because other countries are increasing their patenting faster. Still, there were actual declines in the numbers of West German patents in textile mill products and in total U.K. patents, as well as in U.K. patents in textile mill products and food and kindred products.

The trends in patenting by industry are broadly consistent with the patterns discussed earlier in narrow technology fields. For example, the U.S. strength in the pharmaceutical industry is consistent with U.S. emphasis on biochemical and pharmaceutical technologies. The relative U.S. weakness in the office, computing, and accounting machines industry is consistent with U.S. weakness in photocopying, information storage and retrieval, and typewriting machines. Similarly, U.S. weakness in the transportation industry is consistent with U.S. weakness in the motor vehicles and internal combustion engine technologies.

Citations From Patents to Previous Patents

One criticism of the use of patent counts as indicators of the amount of technical invention is that not all patents are equally significant. If patents could be assigned relative levels of technical or economic significance, it might be possible to interpret better the known differences between the numbers of patents received by different countries in different fields. While there is not yet a broadly accepted way of doing this, one attempted method of gauging the values of different patents involves interpatent citations.

The front page of a patent document usually contains references to previous patents. These references are supplied by the patent examiner as part of the examination process. Cited patents show the "prior art," i.e., the previous achievements in related fields of invention that were taken into account in judging the novelty and significance of the present invention. The patents cited in this way are likely to be the most significant ones in a given field; therefore, the number of citations a patent receives from the front pages of subsequent patents can serve as an indicator of its technical importance.[26]

Citations to Patents, by Country. Data are available on the citations that the U.S. patents granted in a given year receive from all subsequent U.S. patents. It is possible to see which countries have the patents receiving the most and the fewest citations, and in which fields. For example, of the 10 countries that receive the most patents, Japan is

[25]Patenting in these industrial fields was estimated by means of the "Concordance," a computer program maintained by the U.S. Patent and Trademark Office that converts patent counts from the patent office classification system into patent counts in terms of the 1972 SIC system. Patent classes are each associated with the SIC industry that would produce the product or apparatus or would carry out the process steps associated with that class of patents. See U.S. Patent and Trademark Office (1985b), p. 26.

[26]A study of technologically important patents (those connected with innovations that had won the "IR-100" award from *Industrial Research* magazine) showed that, on average, such patents receive twice as many citations as does the average patent. This helps to confirm the validity of interpatent citation as an indicator of patent quality. See Carpenter, Narin, and Woolf (1981). In addition to these examiners' citations on the front of the patent document, there are also citations to earlier patents that the applicant provides within the document. Patents receiving high numbers of examiner citations also tend to receive high numbers of applicant citations. See Carpenter and Narin (1983).

the one whose patents are most often cited. (See text table 6-4a.) This remains true over the period from 1975 to 1985.[27] American patents are cited second most often, with The Netherlands, the United Kingdom, and West Germany following behind. Thus, this appears to be the order of technical significance of the patents granted to these countries.[28]

[27]Text table 6-4 shows a sharp decline in the number of citations per patent from 1975 to 1980, and another from 1980 to 1985. This is because newer patents have had fewer years in which to be cited, not because of any general decline in the quality of patents. Data on citations received per patent are valid as of the end of 1988. Consequently, the data shown for 1985 are especially incomplete.

[28]The frequency with which a country's patents are cited is explained in part by the technical fields in which it receives patents. Interpatent citation is more frequent in some fields than in others, and countries may concentrate their patenting in fields where citation is more frequent or less frequent than the average. Correction should be made for this, since the fields where more interpatent citation occurs are not necessarily fields where patents should be considered more valuable.

The data on text table 6-4 can be adjusted by giving every country the same distribution of patents by SIC field, i.e., the distribution that applies to the United States. If this is done with the 1980 data, the citation frequencies per patent for the different countries are as follows:

- Japan, 3.19;
- United States, 3.09;
- United Kingdom, 2.76;
- The Netherlands, 2.73;
- Switzerland, 2.65;
- Canada, 2.59;
- Sweden, 2.57;
- West Germany, 2.54;
- Italy, 2.50; and
- France, 2.46.

Thus, differences between countries are diminished and there are some changes in the ranking of countries, but Japan remains first and the United States second.

Citations to Patents, by Country and Industry. Since different countries attract citations in different SIC industries, the fields in which a country's patents are more or less significant can be estimated.[29] The fields in which a country's patents are highly cited are often not the same as the ones in which that country receives a large share of patents.[30] For example, patents granted to U.S. inventors in 1980 and 1985 are most highly cited in drugs and medicines and in primary metals and products.[31] While drugs and medicines is a field of outstanding patent activity by U.S. inventors, metals is not. Patents for American inventions receive especially few citations in engines and turbines, in transportation equipment, and in aircraft and parts,[32] all of which are also known areas of weakness in terms of absolute numbers of patents. On the other hand, fields like communication equipment and electronic components and office, computing, and accounting machines, which have dropped greatly in terms of the U.S. share of patents, show average rates of citation with little notable change from 1980 to 1985.[33]

[29]The source for these data is CHI (1989).

[30]Over the list of 55 SIC fields, the correlation coefficient R^2 between numbers of patents and citations per patent is 0.05 or less for each of the 10 countries studied.

[31]These estimates were made by ranking each industry in terms of the citations per patent to U.S. inventors, divided by the citations per patent to *all* inventors. Correction is thus made for different rates of interpatent citation in different fields and also for the lower number of citations per patent in 1985 as compared with 1980.

[32]Patenting data on aircraft and parts are confounded by the difficulty of distinguishing aircraft inventions from those in more conventional transportation technologies, such as motor vehicles. See U.S. Patent and Trademark Office (1985b).

[33]Note again that citation data for 1985 patents are especially incomplete.

Text table 6-4. Citations from U.S. patents to earlier U.S. patents, by country of inventor or sector of owner of cited patents

a. Country of inventor

Year of cited patents	United States	Japan	The Netherlands	United Kingdom	West Germany	Canada	France	Switzerland	Italy	Sweden
	Citations per citable patent									
1975	3.91	4.03	3.63	3.63	3.33	3.33	3.09	2.98	2.99	3.24
1980	3.09	3.35	2.90	2.70	2.51	2.50	2.41	2.37	2.34	2.28
1985	1.37	1.84	1.15	1.21	1.15	1.11	1.07	1.10	1.04	1.02

b. Sector of owner, for U.S. inventors

Year of cited patents	All U.S. inventors	U.S. corporations	U.S. Government	U.S. individuals	Foreign owners
	Citations per citable patent				
1975	3.91	4.15	3.00	3.34	4.13
1980	3.09	3.37	2.41	2.46	3.42
1985	1.37	1.49	1.07	1.02	1.44

Note: Numbers shown will increase, especially those for more recent years, as patents continue to receive more citations.

SOURCE: CHI (1989).

Science & Engineering Indicators—1989

Japanese patents are especially often cited in transportation equipment fields, as well as metal-working machinery, nonelectrical machinery, and refrigeration machinery. Japanese receive relatively few citations in some chemical-related fields, such as soaps and detergents, paints and varnishes, and drugs and medicines; the Japanese share of patents in these fields also tends to be low. On the other hand, Japanese patenting has grown significantly in fields like office, computing, and accounting machines and communication equipment and electronic components. These fields are still not among those most frequently cited for Japanese patents, though citation to them is greater for 1985 cited patents than for 1980 cited patents.[34]

Citations to U.S.-Owned Patents, by Sector of Owner. The patents owned by Americans can be further divided according to the different classes of owners. (See text table 6-4b.) U.S. corporations own the patents that are most often cited, while patents owned by the U.S. Government or U.S. individuals are cited least often.[35] U.S. corporations, in 1975 and 1980, received patent citations as often as Japanese patenters. Since almost all Japanese patents filed in the United States are owned by corporations,[36] it may be more appropriate to compare the citations received by Japanese (and other foreign) patents with those received by U.S. corporation-owned patents. By this measure, U.S. inventors did as well as Japanese inventors in 1975 and 1980. However, the limited data available suggest that this may not be true for 1985.[37] (See text table 6-4.)

Patents granted to U.S. corporations in 1985 were cited especially often in the fields food and kindred products and ordnance, excluding missiles. They were least often cited in railroad equipment and in motorcycles and bicycles and parts.

[34]For 1980 patents, the average Japanese patent has received 1.13 times as many citations as the average world patent. In office, computing, and accounting machines, this ratio is 1.05, and for communication equipment and electronic components, it is 0.99. For 1985 patents, Japanese patents have risen to a citation rate 1.33 times the world average. Patents in communication equipment and electronic components have been cited 1.16 times the world average, and those in office, computing, and accounting machines 1.11 times the world average. Thus, these fields have shared in the rise in citations to Japanese patents, though they still lag behind the average for all fields.

[35]In this case also, the patents with different classes of owners have different distributions by technical field. (Cf. footnote 28.) The 1980 data have again been recalculated using the same distribution, that for the whole U.S., for each owner class. The result is:

- U.S. corporations, 3.32;
- Foreign owners but U.S. inventors, 3.25;
- U.S. individuals, 2.62; and
- U.S. Government, 2.55.

This does not change the ranking of the owner classes, except in the case of foreign owners but U.S. inventors, which represents only a small group of patents. On the other hand, U.S. corporations are now ahead of Japanese inventors for 1980 cited patents.

[36]Additional data from the patent office show that, in 1987, 96 percent of U.S. patents granted to Japanese inventors were owned by "foreign corporations." Virtually all of these corporations would be Japanese. Another 3 percent were owned by foreign individuals, and 1 percent had American owners.

[37]This result is not affected by differences in the U.S. and Japanese distributions of patents by field.

SMALL BUSINESS IN HIGH TECHNOLOGY

The role of small business within the science and technology system has received greater attention as concern grows about the Nation's competitiveness. Small business is widely believed to be highly innovative—responsible for many of the new products and processes introduced into the economy.[38] The creation and growth of small high-tech companies are thus of particular interest as they contribute to the Nation's ability to develop, adopt, and diffuse new technologies.

This section concentrates on small firms operating in high-technology industries. It covers indicators of the activities of small business in high-tech industry overall, as well as providing more detailed information on the financial environment for small high-tech enterprise.

Throughout this discussion, the following terms are used; these follow conventions used by the U.S. Small Business Administration (SBA):

- *Establishment* or *company*—a business entity that may or may not be part of a larger complex.
- *Firm* or *enterprise*—an establishment that is either a single location with no subsidiary or branches, or the topmost parent of a group of establishments.
- *Small business*—firm with less than 500 employees (those with 500 or more employees are described as medium or large).

The definition of high-tech firms is more complex. For this analysis, those industries identified by the Department of Commerce's DOC-3 definition as manufacturing high-tech products are used. By this definition, a high-tech industry must produce products that have an R&D intensity significantly higher than that of other products. R&D intensity is arrived at with the help of an input-output table that includes both the direct and indirect R&D expenditures attributed to a product as a percentage of net sales.[39]

Characteristics of Small High-Tech Enterprises

Small businesses account for 99 percent of all establishments operating in the United States.[40] Although small businesses operating in the high-tech fields comprise a smaller share of the total than they do in the economy as a whole, they still represent almost 89 percent of all high-tech establishments.[41]

[38]In a 1982 study done for the U.S. Small Business Administration comparing innovation between small and large firms, it was found that small firms produced 2.4 times as many innovations as large firms per employee. See Futures Group (1984); Hanson, Stein, and Moore (1984), pp. 105-28; and U.S. SBA (1988), pp. vii-ix.

[39]Indirect R&D expenditures describe the R&D content of input products. For additional information on DOC-3, see U.S. DOC (1983), pp. 33-37. See also the discussion in chapter 7 for a list of industries included in DOC-3.

[40]See Social & Scientific Systems, Inc. (1989).

[41]It is not surprising that small business accounts for a larger share of operating establishments in the rest of the economy than in the high-tech sector. The identification of high-technology industries is based on reported R&D expenditures. Such expenditures are not commonplace in many of the service industries that make up much of U.S. small business (e.g., restaurants, service stations, grocery stores, medical services, etc.).

Distribution of Companies by Field. A data base of high-technology companies, the Corporate Technology (CorpTech) Information Services, Inc., database provides additional information about small businesses currently active in high-tech fields.[42] Companies involved in computer software activities and high-tech service companies each account for 17 percent of the companies in the data base. (See appendix table 6-13.) The next most active field, subassemblies and components, accounted for 10 percent of all companies. Small businesses represented:

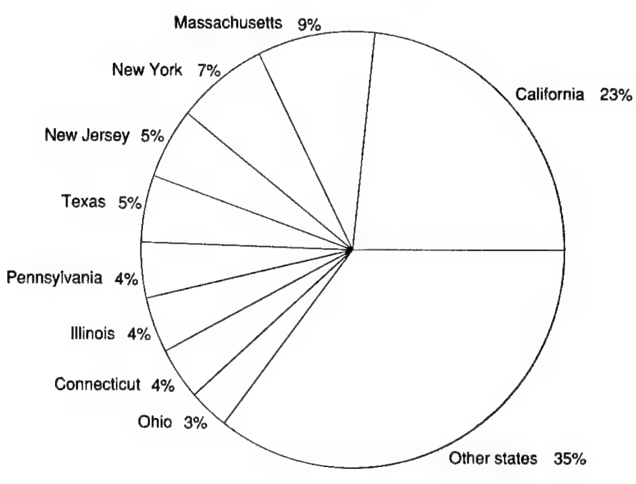
- 98 percent of the firms active in the computer software field,
- 97 percent of firms active in the photonics and optics field, and
- 96 percent of high-tech service firms and tests and measurements firms.

In fact, in 12 of the 17 high-tech fields categorized in the CorpTech data base, small businesses accounted for at least 90 percent of the total active firms within each category. Clearly, small business drives U.S. activity in high-technology areas.

Distribution of Companies by State. Of the 50 states, California can claim the greatest number of small high-tech firms—23 percent. Massachusetts (9 percent), New York (7 percent), New Jersey (5 percent), and Texas (5 percent) also can boast large concentrations of high-technology businesses. (See figure 6-6 and appendix table 6-14.) While California and Massachusetts spawn many new high-tech companies, the data suggest that as these companies grow larger, many merge or are bought out by large firms located outside of those two states. New York, Pennsylvania, Illinois, and Ohio have a higher concentration of large high-tech firms than small; the opposite is true for California and Massachusetts.

[42]The CorpTech data base attempts to be all-inclusive, but—by CorpTech's own estimate—includes only about 50 percent of the total. When prospective companies are identified, they are sent questionnaires covering their size, status (private or public, independent, subsidiary, or joint venture), year formed, and product groups in which they are active. The version of the data base used in this report (version 3.3, March 1989) includes over 30,000 companies.

Figure 6-6.
Small firms active in high technology, by state



Note: None of the "other states" exceeds 3 percent.
See appendix table 6-14. *Science & Engineering Indicators—1989*

Company Earnings and Ownership. Over 40 percent of the small high-tech companies in the CorpTech data base have earnings under $2.5 million. Almost 80 percent earn under $25 million. (See appendix table 6-15.)

In this data base, approximately 11 percent of the high-technology companies operating in the United States are under foreign ownership. (See appendix table 6-16.) The United Kingdom has, by far, the largest U.S. presence, followed by Japan and West Germany, which have an almost equal number of companies under their ownership.

Performance of High-Technology Small Business Establishments

An examination of small companies formed and shut down within industries can give some indication of areas of growth—as well as areas of concern—within the U.S. economy. Taken one step farther, such a comparative analysis within high-technology fields can highlight industries that may need greater attention by policymakers.

Small business establishments operating in high-tech fields prospered better than other small businesses during 1981-86. The high-technology community had a net gain of close to 30,000 establishments during that 6-year period, made possible by a formation/closure rate exceeding 2 to 1. Some 339,000 small business establishments were added in other areas of business, but these gains were realized in a far less successful environment; this was evidenced by a formation/closure rate of 1.2 to 1. (See figure 6-7 and appendix table 6-17.)

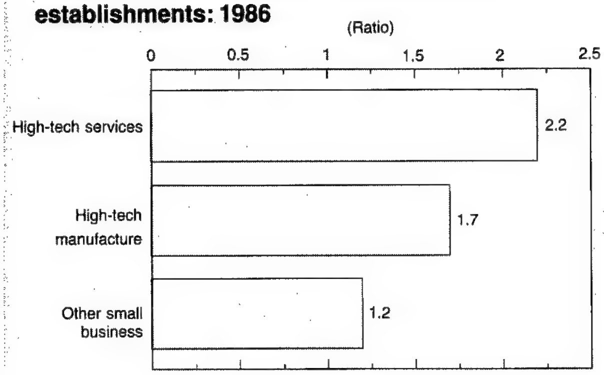
A larger number of technology-related service establishments were formed during 1981-86 than high-tech manufacturing establishments, but the number of closures was not proportionate. This is in part explained by the lower start-up capital generally needed by service businesses; this permits a greater number of formations and greater longevity due to the lower debt burden. Service companies' major investment is usually in human capital which is more adaptable to the unforeseen tuning often required once the market is entered.[43]

During 1981-86, the greatest number of new small manufacturing establishments were created in the communication equipment and electronic component industries, followed by the industries involving professional and scientific instruments. Computer and data processing companies comprised over one-half of all technology-related service firms formed during the 6-year period examined.

Another useful indicator of the level of activity in an economic sector is *employment*. In 1986, small high-tech

[43]For a general discussion of the growth of S/E employment in services and manufacturing sectors, see chapter 3.

Figure 6-7.
Formation/closure ratio for small business establishments: 1986



See appendix table 6-17. *Science & Engineering Indicators—1989*

manufacturing establishments employed more than 739,000 people, up 23 percent from about 600,000 in 1980. (See appendix table 6-18.)

In three technology-related service industries (computer and data processing services; engineering, architectural, and surveying services; and noncommercial educational, scientific, and research organizations), 782,000 people were employed by small business establishments in 1986, compared to 544,000 in 1980—an increase of 44 percent. Employment at technology-related service companies grew faster than in high-tech manufacturing companies: this is more a function of the new service establishments formed during this time than expansion at existing establishments.

A comparison of the gains in employment made in high-tech industries relative to the rest of the economy provides some perspective on their success. (See appendix tables 6-18 and 6-19.) Employment in the technology-related industries overall was 28 percent higher in 1986 than in 1980, while total private sector employment grew by about 11 percent. Concurrently, employment in small business establishments in the technology-related industries grew by 33 percent, while employment in all small businesses grew by 11 percent. The average annual rate of growth in high-tech small business employment during 1980-86 is more than twice the rate of growth in small business employment in the entire U.S. economy.

Despite the gains in numbers employed by small high-tech companies, these companies still account for a substantially lower share of total high-tech employment than is accounted for by small businesses in the U.S. economy as a whole. In 1986, small business establishments accounted for 35 percent of all employment in manufacturing industry in the United States,[44] and about 50 percent of employment in the private sector as a whole. Small high-tech establishments employed 17 percent of total high-tech manufacturing employment and 26 percent of employment at all technology-related establishments during that year.

However, an examination of the new companies formed during 1980-86 suggests that this could change. For each new technology-related small business establishment formed during this period, another eight workers (on average) were employed—compared with seven workers at all other small businesses. Even more encouraging for proponents of high-tech business development is that each new high-tech manufacturing small business establishment added 16 workers on average. The net gain (formations minus closures) in high-technology manufacturing establishments numbered over 6,000 workers, with an average employment of 15.

The apparent vitality of the small high-tech business sector is even more striking when it is considered that some of the businesses that were counted as high-tech small business establishments in 1980 were counted as large businesses by 1986, due to either their growth or their merger with or purchase by other firms. By 1986, 1,195 establishments in the technology-related industries—formerly counted as small businesses in 1980—lost that status either because of internal growth or because merger and acquisition activity had made them parts of larger enterprises. (See appendix table 6-20.) These establishments represent approximately 3 percent of the small establishments that were still operating in technology-related fields in 1986. When viewed against the experience of non-high-tech establishments during 1980-86, small firm establishments in high-tech industries grew out of the small business classification at close to twice the rate of like-sized businesses operating in non-high-tech industries.

The tendency for small high-technology businesses to become medium or large varies considerably among industries. High-technology manufacturing establishments were more likely to grow or merge into large businesses than establishments performing high-tech services; these manufacturing establishments accounted for 55 percent of all technology-related establishments that changed size status, but 67 percent of the gain in employment.

Manufacturing companies that operate in the communication equipment and electronic components industries showed the strongest tendency to leave the small business classification, followed by those companies producing professional and scientific instruments and office, computing, and accounting machines.

Computer and data processing service companies showed a surprising movement out of the small business category, accounting for 289 of the 540 technology-related service companies that expanded and over 23 percent of the employment gains. Technology-related service companies tend to behave like manufacturing companies as they achieve long-term success, they expand and solidify their presence through expansion and merger.

Consequently, if those companies that grew out of the small business classification were included in the examination of the employment gains by high-tech small business establishments during 1980-86, it would show even greater success.

[44]See U.S. SBA (1988), p. 62.

Venture Capital and High-Technology Enterprise

The growth of small businesses and the introduction of new products require access to pools of capital. Compared to larger firms, small businesses—particularly new firms that seek to develop and exploit a new technology—are handicapped by lack of a financial track record and by narrowness of business activities. These factors combine to make it difficult for a firm to secure traditional financial support, i.e., obtain bank loans or sell equity in the stock markets. In the United States, the need for financing for small innovative firms has been at least partially met by a variety of funding mechanisms. These include an active venture capital industry (described below), small-equity markets—such as the NASDAQ listings and markets made by individual stock brokerages—and other financing systems, such as personal funds, funds from wealthy families and individuals, and trust funds.

Venture capitalists make investments in small and young rapidly growing companies that may not have access to public or credit-oriented institutional funding. Their investments may be divided into two classes:[45]

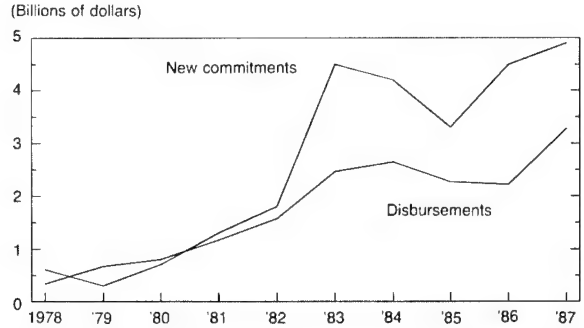
1. *Early stage investments* support the entrepreneur or inventor up through initial commercial manufacturing and sales.
2. *Later stage financing* supports firms that are producing and shipping, but are not yet able to finance substantial expansions and investments in plant. Later stage financing is typically geared toward the sale of stock to the public, known as the initial public offering (IPO).

Most venture capital investments are equity-related, either through direct purchase of stock or through options and other equity-related arrangements. These investments usually emphasize long-term (5- to 10-year) opportunities, and involve the investors closely with the operations of the capital recipient, frequently through participation on the board of directors.

The pool of capital managed by venture capital firms grew dramatically during the 1978-87 period as venture capital emerged as a strong source of finance for small innovative firms. (See figure 6-8 and appendix table 6-21.) In 1987, capital managed by venture capital firms totaled $29 billion; this was eight times the amount available in 1978. During 1983, the total pool of capital grew by 59 percent as a result of a sharp increase in net new private capital commitments. The next 4 years followed the lead set in 1983 and the momentum of the Nation's economic recovery. From 1982 to 1987, the pool grew at more than twice the average annual rate of the previous 4 years.

Faced with declining rates of return in the more traditional investment instruments, pension funds looked to the equity markets for better earning potential and became the source of much of the new venture capital resources.[46] Pension-sourced money committed to venture capital firms grew at a compound annual rate of 64 percent during 1978-86. During the period 1984-86 when foreigners, corporations, and insurance companies reduced funds directed to venture capital firms, pension funds increased theirs at an average annual rate of 24 percent.

Figure 6-8.
Venture capital commitments and disbursements: 1978-87



See appendix table 6-21. *Science & Engineering Indicators—1989*

During the last 5 years studied, new capital commitments exceeded disbursements by the venture capital industry, even when debt financing and leveraged buyout financing are taken into account. Thus, there is apparently a surplus of venture funds seeking outlets in new or expanding innovative firms. But the venture capital industry is highly sensitive to changes in both the economy and the political environment (e.g., treatment of long-term capital gains). For example, if data were available on a quarterly basis, there would most likely be a sharp decline during the fourth quarter of 1987 and during 1988 following the market crash on October 19, 1987.

Throughout the period 1984-87, firms producing computer and computer-related products received the largest—albeit declining—share of both early and later stage investments. Other industries that received substantial venture capital investments were the communications industries and those producing electronic components and other electronic products (including instruments).

IPOs are another indicator of new firms' financial development. At this stage, a firm is presumably well enough established—either through access to superior technology or through actual production and sales capability—that it can raise money through the stock market. Funds raised in this manner increased erratically during the 1984-87 period. (See appendix table 6-23.) IPOs generated $478 million for small firms in 1984 and $345 million in 1985; they then jumped to $1.4 billion in 1986 before dropping back to $1.2 billion in 1987.

High-tech industries met with varying degrees of success with IPOs. The computer and computer-related industry received the bulk of such investment reported in 1984—54 percent of all venture-backed IPOs generated by small businesses. Its share has declined steadily since then, however, accounting for 25 percent in 1987. During 1987,

[45]The definitions and discussion used here are based on Venture Economics, Inc. (1988).

[46]See U.S. DOC (1988), p. 54-3.

commercial communications, telephone, and data communication firms were able to attract almost four times the dollars raised the previous year. The "information boom" continues to provide an incentive for investment in firms specializing in products that facilitate the compilation and transfer of data.

Small Business and Biotechnology

The biotechnology industry is a particularly good vehicle for analyzing small business in the S&T system. It is an industry that has a large science component, using techniques such as recombinant DNA and hybridomas that are the continuing subject of intensive work in university and private basic research laboratories. Also, it is an industry that—considering its small size—performs a significant and increasing amount of R&D, employing thousands of scientists and engineers.[47]

According to the CorpTech data base, there were 717 companies and 438 independent firms active[48] in the various fields of biotechnology during 1988; of these, 414 would be classified as "small business" using the SBA criterion. The vast majority of the small companies active in biotechnology are privately held businesses. More than half of the companies are involved in either genetic engineering and/or producing equipment for the biotech industry. Before 1980, only 371 biotech companies were formed in the United States—346 have been formed since then.

Small biotechnology companies sometimes look to R&D contracts for revenues and leave the larger firms responsible for bringing the products that evolve to market. For example, small companies have contributed significantly in the development of recombinant DNA drugs, but have most often sold the rights to these products to large firms that have the internal structures in place to bring the product successfully to the marketplace.[49]

While revenues have climbed dramatically over the last few years (from $60 million in 1984 to $500 million in 1987), earnings of billions of dollars are often projected for the early 1990s. With the aging of the populace and the proliferation of the AIDS virus, health care is touted as the field from which biotechnology will derive its greatest revenues over the next couple of years.[50]

Biotechnology (including recombinant DNA, monoclonal antibodies and hybridomas, and other genetic engineering) has received small, but increasing, amounts of venture capital during the years for which data are available, receiving about $63 million in early and later stage investment in 1984 and $206 million in 1987. In 1986, there was a surge of venture-backed IPOs by biotechnology firms, with almost $270 million raised, or 19 percent of the total capital raised in this fashion. In 1987, however, financial resources raised through IPOs by biotechnology firms were cut in half. Firms in most other high-tech fields fared better. (See appendix tables 6-22 and 6-23.) The erratic experience with IPOs is a reflection of the rollercoaster expectations that the marketplace has ascribed to the biotechnology industry.

The 3 years following 1985 have shown a steady decline in new biotech companies. Whereas some of the decline can be attributed as a correction to the past surge in growth, the industry is facing some difficult problems that are also contributing to the slowdown.

The projected market values of biotechnology breakthroughs have fallen short of expectations as the reality of bringing the new products to market encounters cost-adding and time-consuming hurdles such as protracted periods of testing and government scrutiny that can delay market entry. Patent infringements—especially foreign violations—are becoming more commonplace[51] and are siphoning off revenues that could support growth and new research in the industry.

The biotechnology industry provides a microeconomic perspective of small business that has its origin in, and whose continued existence is dependent upon, new science and technology. It is an industry whose products have generated a great deal of interest and controversy in many sectors of society. As the industry matures, it will be interesting to observe whether small companies can continue to prosper in a business environment that is certain to become more litigious and, consequently, more cautious about the industry's outputs.

[47]R&D performed at firms active in biotechnology increased by over 50 percent during 1984-87, reaching an estimated $1.4 billion in 1987. See NSF (1988b).

[48]"Activity" means either production, sales, or R&D activity in the fields defined by the data base as biotechnology.

Chapter 7
The Global Markets for U.S. Technology

CONTENTS

The Global Markets for U.S. Technology

HIGHLIGHTS

- *During the period 1970-86, the United States was consistently the leading supplier of high-technology products in the global marketplace.* But its lead position declined from a 51-percent share held in 1970 to its 42-percent share in 1986. Japan doubled its global market share during this period, rising from 16 percent in 1970 to 32 percent in 1986. (See p. 150.)
- *The United States is the world's largest market for high-technology goods, consuming almost half of the high-tech products sold globally.* While U.S. producers were the dominant suppliers to the domestic market during 1970-86, they gradually and consistently lost market share to foreign producers. (See p. 151.)
- *The United States exports a far lower share of its high-technology products (15 percent of its high-tech production in 1986) than do other industrialized countries (West Germany, 61 percent; United Kingdom, 54 percent; France, 38 percent; and Japan, 22 percent).* Still, the United States was the world's leading exporter of high-tech products until 1986, when it was overtaken by Japan. (See p. 152.)
- *The U.S. trade surplus in high-tech goods declined steadily during the 1980s, and suffered its first trade deficit in 1986.* In 1987, the United States once again registered a small trade surplus in high-technology goods, with U.S. exports of aircraft and related parts leading the way. (See p. 153.)
- *U.S. high-technology manufacturing firms maintain a significantly higher portion of their assets in foreign affiliates (42 percent of total assets) than do other U.S. manufacturers (30 percent).* U.S. manufacturers' foreign affiliates are concentrated in Europe. In addition to equity investments in foreign affiliates, U.S. high-tech multinationals enter into agreements with foreign firms to have them supply parts and components to support production opportunities back in the United States. Data on this aspect, however, remain anecdotal. (See p. 155.)
- *The United States licenses considerably more technological know-how to foreign firms than it buys.* U.S. receipts from the sale of patent licenses to foreigners have been, on average, four times that paid out by U.S. firms for access to foreign technological know-how. Japan is by far the largest customer, accounting for 41 percent of such U.S. revenues in 1987. (See p. 156.)

The global marketplace can be considered the commercial proving ground for a country's science and technology (S&T). It is in the marketplace that technological advances in the form of new products or processes are evaluated.

A major share of the U.S. research and development (R&D) effort is accounted for by private firms using private funds. The presumed goal of these investments in S&T is to develop a technological advantage that can be exploited profitably. Research and development are expensive activities that require firms to commit substantial resources over extended periods of time and to assume the risk should these investments not prove profitable. Private R&D investment, which accounts for about one-half of total U.S. R&D, is ultimately judged by the successes and failures of its outputs—new products and processes.

Private financing of the innovation process depends on firms' access to markets and on their expected success in earning sufficient returns on R&D investments to justify further investment in R&D. Well-functioning markets provide the monetary rewards for "good science and engineering" when these efforts lead to technology that is accepted in the marketplace.

U.S. competitiveness in the global marketplace engenders the widespread concern regarding the ability of U.S. producers both to export and compete against imports in their home market. The U.S. S&T system plays an important role in U.S. competitiveness.[1] Skilled and timely exploitation of emerging technological possibilities clearly contributes to the Nation's competitiveness by generating lower costs and new and better quality products. Examination of U.S. firms' performance in the global marketplace provides useful indicators to identify strengths and weaknesses in the Nation's S&T system.

This chapter brings together several data sets describing the domestic and foreign markets for U.S. technology so as to examine the activities of U.S. firms in the global marketplace—particularly in high-technology areas—and thereby assess the relative strength of U.S. industry in global competition.

[1]Milberg (1988) argues that an industry's innovativeness is dependent upon progressive R&D expenditures, and that such expenditures should be considered a necessary investment to support its position in the global marketplace.

U.S. COMPETITIVENESS IN THE MARKETPLACE

The large U.S. trade deficits of recent years have focused attention upon the country's international economic competitiveness. In 1986, for the first time ever, the U.S. balance of trade in high-tech goods was negative, prompting increased concern about the role of science and technology in supporting and restoring U.S. leadership in the global marketplace.

The relationship between S&T and market competitiveness is circular: science and technology support U.S. competitiveness in the national and international trading system, and commercial success in the global marketplace provides resources to help support new science and technology.[2] The contribution of research and development and other science and engineering (S/E) activities to the Nation's economic performance is therefore indirectly measured by its success in the global marketplace.

This section discusses "competitiveness," broadly defined as the ability of U.S. firms to sell products in the global market. The analysis draws heavily on data compiled by the Organisation for Economic Co-operation and Development (OECD) and the U.S. Department of Commerce (DOC). OECD compiles data from 25 advanced industrialized countries including the United States, Japan, and the European Community.[3] These data are presented for all manufactured goods and high-tech products.[4, 5]

Researchers have used several methods to identify individual industries or product groups as "research intensive" or "high technology." These methods usually employ some measure of the R&D effort undertaken in the industry or product group, normalized for industry size.[6] In some industries, however, the relevant R&D is performed internally; in others, firms depend upon the innovations of those upstream suppliers that provide input to their production processes.

Both OECD and DOC identify high-tech products as those that have higher ratios of R&D expenditures to shipments than do other product groups. The OECD classification used in this analysis is called "high intensity technology products"; it relies on directly applied R&D expenditures in its calculation and includes those products with above average R&D intensities. Direct R&D expenditures are those made by the firms in the product group. High-technology industries identified by OECD's definition—and their respective international standard industrial classification (ISIC) codes—are:

- Drugs and medicines (ISIC 3522);
- Office machinery, computers (ISIC 3825);
- Electrical machinery (ISIC 383 less 3832);
- Electronic components (ISIC 3832);
- Aerospace (ISIC 3845); and
- Scientific instruments (ISIC 385).

The Department of Commerce definition, also used in this analysis, identifies high-tech products as those products that have significantly higher ratios of direct and indirect R&D expenditures to shipments than do other product groups. Indirect R&D describes the R&D content of input products.

To address this complicated technological structure, DOC uses an input-output table to allocate the applied research and development expenditures of intermediate-goods producers among the final-goods producers. This allocation, when normalized by shipments, permits identification of those groups of products whose total R&D intensity is significantly higher than that of other products. These product groups are known collectively as the DOC-3 high-technology products.[7] DOC-3 industries, and their respective Standard Industrial Classification (SIC) codes, are:

- Guided missiles and spacecraft (SIC 376);
- Communication equipment and electronic components (SIC 365-367);
- Aircraft and parts (SIC 372);
- Office, computing, and accounting machines (SIC 357);
- Ordnance and accessories (SIC 348);
- Drugs and medicines (SIC 283);
- Industrial inorganic chemicals (SIC 281);
- Professional and scientific instruments (SIC 38 excluding 3825);
- Engines, turbines, and parts (SIC 351); and
- Plastic materials and synthetic resins, rubber, and fibers (SIC 282).

[2]Dornbusch, Porteba, and Summers (1988) describe a higher propensity by manufacturing firms to invest in research and development than firms in other sectors of the U.S. economy. They point out that "manufacturing companies invest 90 times as large a share of their value added in R&D as do companies in other sectors."

[3]The 25 countries reporting to OECD are: Australia, Austria, Belgium/Luxembourg, Canada, Denmark, Finland, France, Greece, Iceland, Ireland, Italy, Japan, The Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, Turkey, the United Kingdom, the United States, West Germany, and Yugoslavia (Yugoslavia participates in OECD with a special status).

[4]The OECD data are expressed in current U.S. dollars at official exchange rates. Fluctuations in the currency exchange rate and differences in the price levels between each country and the United States can distort cross-country, time-series comparisons for products isolated from foreign competition.

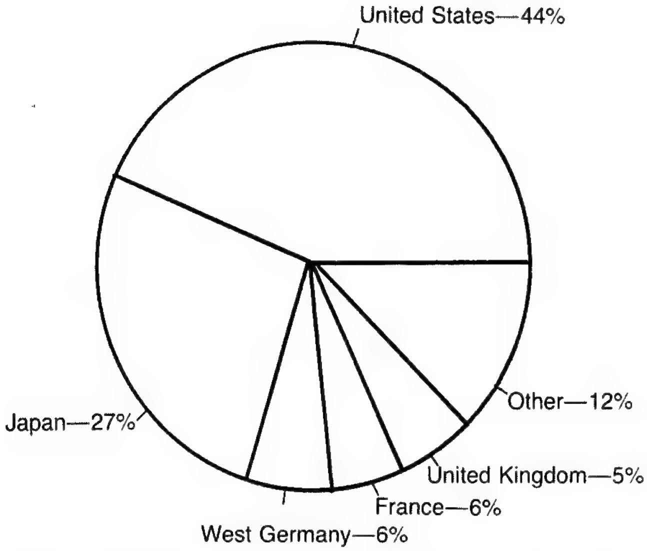
Most manufactured products of the United States and the other OECD countries are exposed to foreign competition in their home markets as well as in foreign markets, thereby reducing the effect currency fluctuations will have on measurement of trade flows. Furthermore, in the following discussion, care has been taken to minimize any distortions caused by the terms of value used. Where distortions cannot be avoided, trends are appropriately qualified.

[5]Data used in this chapter are compiled by government agencies and international organizations. These data benefit from ongoing efforts by the collectors to employ uniform definitions and standards. To account for any remaining slight differences among countries' definitions, concepts, and data collection and reporting practices, attention here is primarily on trends and significant fluctuations in data levels.

[6]R&D expenditures as a percentage of total sales, and scientists and engineers employed in R&D as a percentage of total employment, are two prominent examples of this approach. See Boretsky (1982) and Kelly (1976).

[7]See Davis (1982).

Figure 7-1.
Home markets of major industralized countries as a percentage of the global market for high-tech products: 1986



See appendix table 7-4. *Science & Engineering Indicators—1989*

Comparisons of U.S. production data for "high intensity technology products"— as reported to OECD—with U.S. total shipment data for "high-technology" products—as reported to the Department of Commerce according to the DOC-3 definition— show that OECD data represented 96 percent and 100 percent of DOC-3 data in 1980 and 1986, respectively.

The Global Market for High-Technology Products

The U.S. home market is the largest market for high-tech goods in the world. (See figure 7-1.) Consequently, an assessment of U.S. competitiveness in high-tech goods cannot be evaluated by our trade competitiveness—i.e., a comparison of our exports with our imports—alone. Rather, we must examine the country's ability to sell high-tech products globally and domestically.

The global market for high-tech products is growing at a slightly faster rate than the market for other manufactured goods. (See appendix tables 7-1 and 7-3.) During the 1970s, high-tech products represented approximately 12 percent of global production of all manufactured goods.[8] During the 1980s, the global market for high-technology goods increased faster than the global market for other manufactured goods, and accounted for 16 percent of total production by 1986.

[8]Production data, compiled by OECD, are used in lieu of shipment data to estimate the global market for high-tech and other manufactured products. OECD does not collect data on either shipments or changes in inventories; if inventory data were available, shipment data could be calculated from production data. Production data provide a reasonable approximation of worldwide activity, especially for trend analysis.

Over the period examined, 1970-86, the United States clearly reigned as the leading producer of high-tech products, although its position was being challenged. During the 1970s, U.S. global market share declined as Japan, West Germany, and France each increased their production of high-technology products at a faster rate than did the United States. After 1980, the U.S. share increased and—by 1985—approached its previously held level. In 1986, however, U.S. market share fell once again, losing to Japan and West Germany.[9] (See figure O-22.)

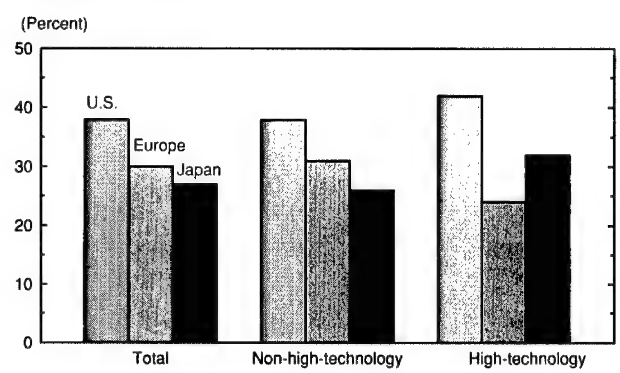
Japan's global market share, by contrast, increased during 1970-86—rising from a 16-percent global market share in 1970 to 32 percent by 1986. European producers' global share declined steadily over the period, dropping from a peak of 36 percent in 1975 to a low of 21 percent in 1985. West Germany led European producers in 1986 with a 7-percent market share, compared with 5-percent shares for France and the United Kingdom.[10] (See figure 7-2 and appendix table 7-1.)

As would be expected of major industrialized economies, the U.S., Japan, and Europe have increasingly moved productive resources toward the manufacture of more sophisticated, higher value, technology-related goods and away from more labor intensive products. In 1986, the value of U.S. high-tech products represented 17 percent of total production, up from 13 percent in 1975; high-tech products accounted for 13 percent of Europe's total production in 1986, compared with 10 percent in 1975. (See appendix table 7-3.) But it was Japan that made the greatest

[9]The fall in the U.S. dollar vis-à-vis the currencies of the other major industrialized countries exaggerates this fall somewhat.

[10]Fluctuations in price levels and exchange rates affect these year-to-year comparisons. If these data could be adjusted to correct for such fluctuations, the relative positions of the United States and Japan would not change, whereas the individual positions of the European countries might realign somewhat. Japan's and West Germany's production are probably overstated to some degree and France's and the United Kingdom's production are probably understated. (See appendix table 7-2.)

Figure 7-2.
Global market shares for manufactured products: 1986



Note: Production data compiled by OECD are used to estimate the global market for manufactured products.
See appendix table 7-1. *Science & Engineering Indicators—1989*

transitional leap foward in this respect, pulling even with the U.S. in 1982 and surpassing it thereafter.

The U.S. Market for High-Technology Products

A country's home market is often thought of as the natural destination for its manufactured output. For obvious reasons, marketing at home is easier than marketing abroad—e.g., proximity to the customer, common language, customs, and currency—and other advantages.

But in today's global marketplace, the most competitive product—almost regardless of its origin—wins the sale. When many sellers exist, the most competitive product is determined by its price, quality, and ability to satisfy the customer's needs. Buyers of most goods—but especially of high-technology goods—may weigh these factors differently, but ultimately will choose based on consideration of these elements. Thus, in the absence of prohibitive trade barriers, a country's home market is not a private domain for its native producers, and therefore needs to be included in the equation when examining global competitiveness.

Comparison With Other Markets. As stated earlier, the U.S. market is the single largest market for the world's production of high-tech goods. (See appendix table 7-4.) The U.S. market purchased over half of global production in 1970, with Japan—a distant second—consuming 15 percent. During the 1970s, other countries' home markets grew faster than that of the United States, especially markets in Japan and France: U.S. consumption fell to 41 percent of worldwide consumption, while Japan's market represented almost 20 percent and France as high as 9 percent.

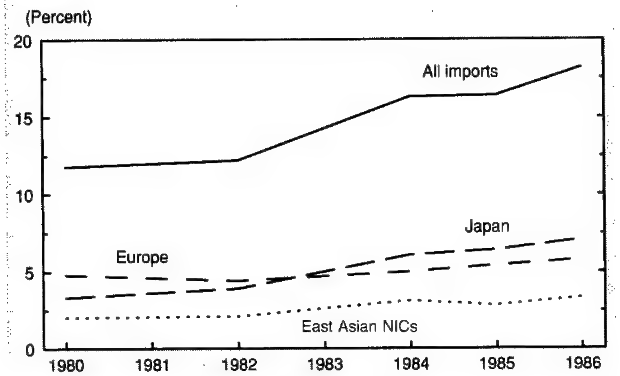
But the 1980s brought with it a realization that U.S. competitiveness in the global market was eroding. One reason for this was deficient manufacturing systems. In response, U.S. industry began to retool its factories and mechanize many tasks formerly done manually. Subsequently, the 1980s saw a resurgence in consumption of high-tech goods in the United States. During 1980-85, the U.S. market for high-technology products increased sharply, which left the relative size of other developed countries' markets to decline in comparison or—as in Japan—fluctuate downward.

U.S. Market. U.S. producers of high-tech products benefitted from having their home market grow at such a pace; shipments within the United States increased over 50 percent during 1980-86. But imports were attracted as well and, encouraged by a strong U.S. dollar, supplied an increasing share of total U.S. high-technology purchases. (See figure 7-3 and appendix table 7-6.)

Imports supplied about 12 percent of U.S. purchases of high-tech products in 1980, rising steadily to 18 percent in 1986. During 1980-86, Japan increased its U.S. market share faster than other suppliers, ultimately doubling its position in the U.S. market for high-technology products. In 1980, U.S. purchases of Japanese high-tech products represented 3.3 percent of total U.S. consumption; by 1986, this had jumped to 7.1 percent.

European suppliers also increased market share during the 1980s, though they were far less successful than Japan.

Figure 7-3.
U.S. imports of high-tech products as a percentage of the U.S. market: 1980-86



Note: East Asian NICs include Hong Kong, Singapore, South Korea, and Taiwan.
See appendix table 7-6. *Science & Engineering Indicators—1989*

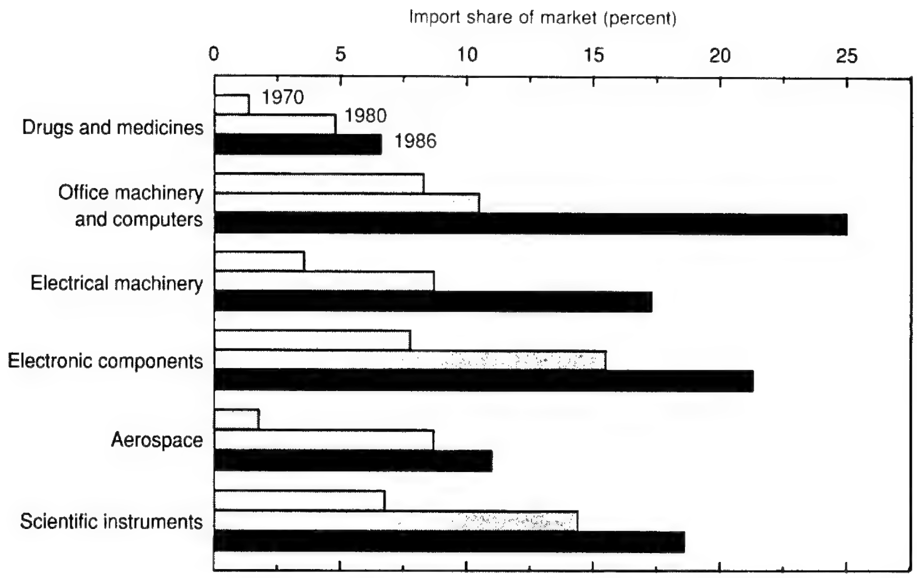
The East Asian newly industrialized countries (NIC)—which include Hong Kong, Singapore, South Korea, and Taiwan—increased their presence in the U.S. market as well, supplying 3.3 percent of U.S. consumption of high-tech products in 1986, up from 2.0 percent in 1980.

A more detailed examination of the U.S. high-technology product market shows foreign producers gaining market share in all sectors. (See figure 7-4 and appendix table 7-7.) By 1986, foreign producers supplied over 20 percent of U.S. consumption of computer products and electronic components. Of all the high-tech sectors, the aerospace industry experienced the greatest rate of increase in foreign competition in the U.S. market as imports' U.S. market share rose from under 2 percent in 1970 to 11 percent in 1986.

Other Countries' Home Markets. The U.S. market is not alone in its increased reliance on foreign technologies. From 1970 to 1986, while European producers of high-tech products steadily increased their shipments to their respective home markets, they still consistently lost market share to foreign suppliers. (See appendix table 7-5.) In fact, European producers' lost home market share was far more dramatic than that experienced by the United States. (See figure 7-5.) For example, in 1970, the United Kingdom's producers supplied 83 percent of their home market for high-technology products; by 1986, they supplied only 46 percent. West German producers' share of their high-tech market was 77 percent; this dropped to 45 percent by 1986. French high-technology producers fared better, but also lost market share to foreign producers as their share declined from 77 percent in 1970 to 62 percent in 1986.

Of the major industrialized countries, only Japan's producers were able to hold domestic market share. In a market that experienced substantial growth during 1970-86, Japanese producers of high-tech products increased shipments to their home market accordingly and thereby

Figure 7-4.
Import penetration of certain U.S. high-tech markets: 1970, 1980, and 1986

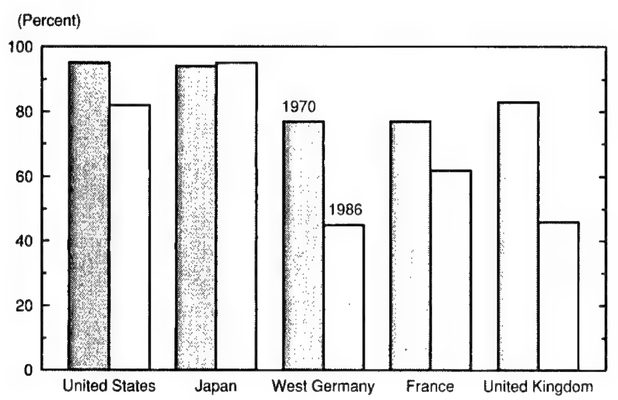


See appendix table 7-7. *Science & Engineering Indicators—1989*

maintained market share of 93 percent to 95 percent throughout the 16-year period.

Summary. The U.S. home market has shown considerable growth during the 1980s and has attracted increasing amounts of the world's production of high-tech goods—including that of U.S. manufacturers. The data appear to support the notion that the United States is a highly attractive market for the world's producers of high-technology goods. U.S. producers of high-tech products still maintain a dominant position in their home market, but that position is being challenged by foreign manufacturers.

Figure 7-5.
Shares of home markets for high-tech products supplied by domestic producers, for major countries: 1970 and 1986



See appendix table 7-5. *Science & Engineering Indicators—1989*

Foreign Markets for High-Technology Products

Historically, the United States has not been an economy oriented toward serving foreign markets. The sheer size of the U.S. economy provided the U.S. business community with large markets that supported its operations and generally encouraged its expansion.[11] Consequently, U.S. commerce looked to overseas markets mostly as an afterthought. Mounting trade deficits, however, are now inciting interest in expanding U.S. exports. This section examines U.S. technology sales in foreign markets and the role exports have played over the years.

The U.S. Experience. U.S. producers are important suppliers of high-tech products in the overseas market, but they have not been able to increase their market share to any significant degree.[12] A comparison of U.S. producers' share of the foreign market for high-technology products in 1970 and 1986 shows a gain of only 1 point, from 10 percent to 11 percent.[13] (See appendix table 7-8.)

---

[11]See Council of Economic Advisers (1989), pp. 234-38.

[12]Foreign markets are calculated by subtracting total U.S. consumption of high-tech products from OECD production of high-tech products.

[13]The exchange rate between the U.S. dollar and a trade-weighted average for the currencies of the other major industrialized countries was fairly stable for these 2 years.

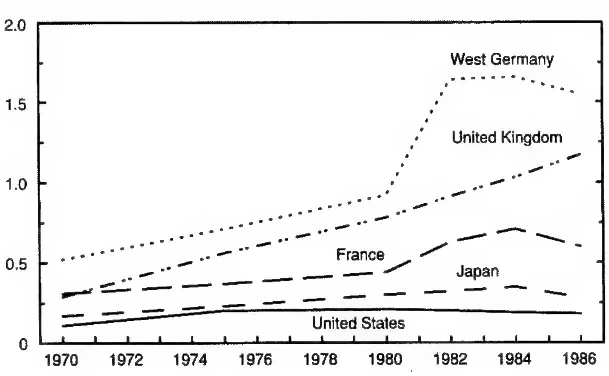
The United States consistently exported a larger share of its high-technology manufactures than non-high-technology manufactures. (See appendix table 7-9.) In 1978, about 18 percent of U.S. shipments of high-tech products were exported, compared with 4.5 percent of non-high-tech manufactured products. By 1986, the gap closed somewhat; high-tech exports still represented close to 18 percent of total high-tech shipments, but non-high-tech exports increased to almost 6 percent of total non-high-tech shipments.

Experience of Other Countries. By contrast, U.S. competitors have long emphasized exports of their high-technology products. (See appendix table 7-12.) In 1986, the United States exported 15 percent of its high-tech production, compared with 22 percent by Japan and substantially higher levels by the European countries.

Comparing each country's exports to its domestic shipments reveals the role foreign sales have played in each country's high-tech industries. During 1970-86, all of the other major industrialized countries exhibited comparatively greater tendencies to export than did the United States. (See figure 7-6 and appendix table 7-13.) West Germany's exports of high-technology products increased from half the size of its domestic sales in 1970 to 1.5 times its domestic shipments by 1986. Exports by the United Kingdom of high-tech products exceeded its domestic shipments of such products starting in 1984 and did so each year thereafter. France, with a home market comparable in size to that of West Germany, is less export-oriented than other European countries, but nevertheless had a much higher export/domestic shipment ratio than the United States.

Like that in the United States, Japan's strong home market for high-technology goods absorbed a larger share of its high-tech shipments than that accounted for by sales to foreign markets. Still, Japan's high-technology industry is considerably more export-oriented than is U.S. industry.

Figure 7-6.
Ratio of exports to domestic shipments for high-tech products, by country: 1970-86



See appendix table 7-13. *Science & Engineering Indicators—1989*

In 1986, the ratio of Japanese exports of high-tech products to domestic shipments was 0.3 to 1, up from 0.2 to 1 in 1970. In comparison, the U.S. export/domestic shipment ratio followed an irregular trend during the 16-year period examined. Even at its peak in 1980, it did not exceed 0.2 to 1.

U.S. Exports by Sector. While it is apparent that U.S. domestic sales of high-tech products far exceed its exports, that tends to obscure what continues to be a strong demand for U.S. high-technology products in foreign markets. In fact, the United States was the world's leading exporter of these until recently, when it was overtaken by Japan. (See appendix table 7-10.) In 1986, Japan supplied 24 percent of world exports of high-technology products; the United States' share was 22 percent.

Throughout the period examined (1978-86), exports of aircraft and related parts topped the list of U.S. high-tech exports, followed closely by exports of communication equipment and electronic components and of office and computing machines. (See appendix table 7-9.) Together, these three high-tech product groups account for a large and increasing share of all U.S. high-technology exports (68 percent in 1986, up from 60 percent in 1978), as well as of all manufacturing products (29 percent in 1986, 22 percent in 1978). Exports of computers and related equipment (office and computing machines) showed the most growth among the high-technology products, registering a threefold increase during the 1978-86 period.[14]

From 1976 through 1985, the United States maintained a consistent trade surplus for the identified high-tech product groups, and imported more than it exported of other manufactured products. (See appendix tables 7-14 and 7-15.) Since 1980, U.S. high-tech exports have continued to grow, but U.S. imports have grown faster. As a result, the U.S. high-technology trade surplus has declined substantially, dropping from about $27 billion in 1980 to under $4 billion in 1985. In 1986, the United States experienced its first trade deficit in the high-technology sector, with exports of $72.5 billion and imports of $75.1 billion. During 1987, U.S. trade in high-technology products (exports plus imports) jumped close to 14 percent over 1986, and returned to a slight surplus position as exports, once again, exceeded imports.

By contrast, the U.S. balance of trade for non-high-technology goods has been in deficit since 1975. During the 1980s, the U.S. annual trade deficit in this sector grew dramatically from $4.7 billion in 1980 to over $138.0 billion in 1987.

Summary. U.S. industries with high levels of R&D activities apparently maintain a comparative trade advantage—although this advantage is weakening. By inference,

[14]Companies in these three product groups also were particularly intensive in their R&D performance. In 1985, company-funded R&D expenditures in the industries associated with these products were about $19 billion, or almost 37 percent of the total industry-funded R&D effort in the United States. (See NSF, 1986.) Moreover, this measure probably understates the importance of these industries to the U.S. commercial R&D endeavor, since they also provide important markets for a variety of high-technology inputs and encourage R&D expenditures in various supplier industries.

those U.S.-manufactured products that contain high levels of R&D inputs seem to be more competitive in foreign markets than do non-high-tech U.S. products. Increased competitiveness overseas provides additional revenues; this in turn provides resources for new private investment in R&D. The circular path of reinforcement of science and technology and U.S. competitiveness can be aided by success in foreign markets.

INDIRECT CHANNELS FOR INTERNATIONAL DIFFUSION OF U.S. TECHNOLOGY

Profitable international diffusion of an innovation—whether through *exports, affiliate sales,* or *licensing* to a foreign producer—helps to finance and justify the innovator's R&D expenditures and thereby encourage new innovative activities. This section examines the trends of technology diffusion by U.S. firms through their various investments in foreign markets.

U.S. Direct Investment Abroad

Motivation for U.S. Foreign Investment. One way U.S. firms sell or transfer their products in foreign markets is by establishing production facilities in other countries. U.S. high-tech firms establish overseas operations in an effort to maximize revenues by exploiting all avenues to enhance the firm's ability to compete.

Firms establish overseas operations for many diverse reasons—to take advantage of lower operating costs, to avoid tariffs and/or other nontariff barriers in the host country, to better serve a market in which they have already achieved some success to name a few. The decision to invest overseas also may be related to the technology's age, with innovations initially exploited through exports, and production moving offshore as the product or process matures.[15]

Relative costs of production in the United States and in foreign countries are another factor. When production costs are substantially lower outside the United States, some level of production will, in time, be shifted overseas. These foreign affiliates will then tend to serve that country and region and may even replace U.S. production, especially for mature products whose manufacture incorporates readily available technical expertise and equipment. The movement toward such global manufacturing involves not only the manufacture of final products, but increasingly of parts and components that are then used to support final product manufacturing back in the United States.[16]

When a high-tech firm establishes a facility offshore, it expects to exploit some advantage it possesses, generally in the uniqueness of its product or its ability to service a market. New technologies and innovations generally are not transferred overseas until the later stages of the product cycle. By inference, these investments in foreign affiliates involve technologies that were introduced years before.

How much technical expertise or know-how is actually transferred when facilities are established overseas depends on the state of development of the prospective host country, with lesser developed countries having the potential for the greatest gain through both direct and indirect transfers of technology. Indirect technology transfers occur through the training of technicians and managers that result, and through the technical knowledge transferred to firms that support the facility and to customers trained in the use of the product. On the other hand, when developed countries are host to such foreign investment, they primarily get another competitor for their own production of similar high-tech products.

The data used in this section measure the book value of U.S. investors' equity in and outstanding debt with affiliated firms overseas.[17] While these data do not provide any information about the kind of investment, they do indicate both the level and location of U.S. commercial ties abroad.

Trends in U.S. Direct Investment. U.S. direct investment abroad in manufacturing industries exceeded $92 billion by 1981; this represents almost a threefold increase since 1970. (See appendix table 7-16.) After 1981, the uninterrupted growth in the U.S. foreign investment position stalled, thereafter following a more erratic path. As the United States slipped into recession after 1981, U.S. firms' investment position abroad declined. By the next year, it was down about 10 percent. This dip continued through 1984. By the end of that year, however, direct investment abroad began an upward trend that continued through 1987. The U.S. direct investment position in manufacturing industries abroad increased 21 percent from 1986 to 1987; this was about twice the rate of increase recorded in the prior 2 years.

This pattern was also mirrored by the two high-tech industries for which data are available—the chemicals and allied products and machinery manufacturing industries[18]—although the upward trend began a year earlier during 1983. The bulk of the increase between 1986 and 1987 is attributable to reinvestment of 1987 earnings, which were nearly double the level reported during 1986. These improved earnings were due to the effects of the dollar depreciation and enhanced operating profits, which in turn derived from strong demand and an improvement in operating efficiencies after some corporate restructuring.[19]

[15]See Vernon (1966) and Hufbauer (1966) for more extensive discussion of the "product cycle."

[16]In addition, U.S. multinationals are, with increasing frequency, entering into agreements with individual foreign manufacturers to have them supply parts and components that were formerly manufactured in the United States.

[17]These data measure the book value of U.S. direct investors' equity in, and net outstanding loans to, their foreign affiliates. "Affiliates" are firms in which the reporting U.S. parent holds an interest of at least 10 percent of the voting securities, or the equivalent. See U.S. DOC, Bureau of Economic Analysis (1985); and U.S. DOC, Bureau of Economic Analysis (1987).

[18]Includes the nonelectrical machinery and electric and electronic equipment industry groups.

[19]Scholl and Lowe (1988).

The geographical location of U.S. investment in overseas subsidiaries has changed substantially over the years, shifting away from Europe and toward the Asian-Pacific countries. (See appendix table 7-16.) In 1966, U.S. direct investment in Canada and the United Kingdom made up nearly 50 percent of the total U.S. direct investment position abroad in manufacturing; by 1987, this combined investment had declined to 35 percent. In 1966, West Germany and France were each host to three to four times as much U.S. direct investment as Japan for all manufacturing industries, and about twice as much as in the machinery and chemical industries. By 1987, however, the comparable U.S. direct investment position in Japan grew considerably, and in fact actually exceeded that in West Germany and France in the high-technology manufacturing industry of chemical products. Other Asian-Pacific countries also received larger amounts of U.S. direct investment between 1966 and 1987 as did Mexico and other lesser developed countries.

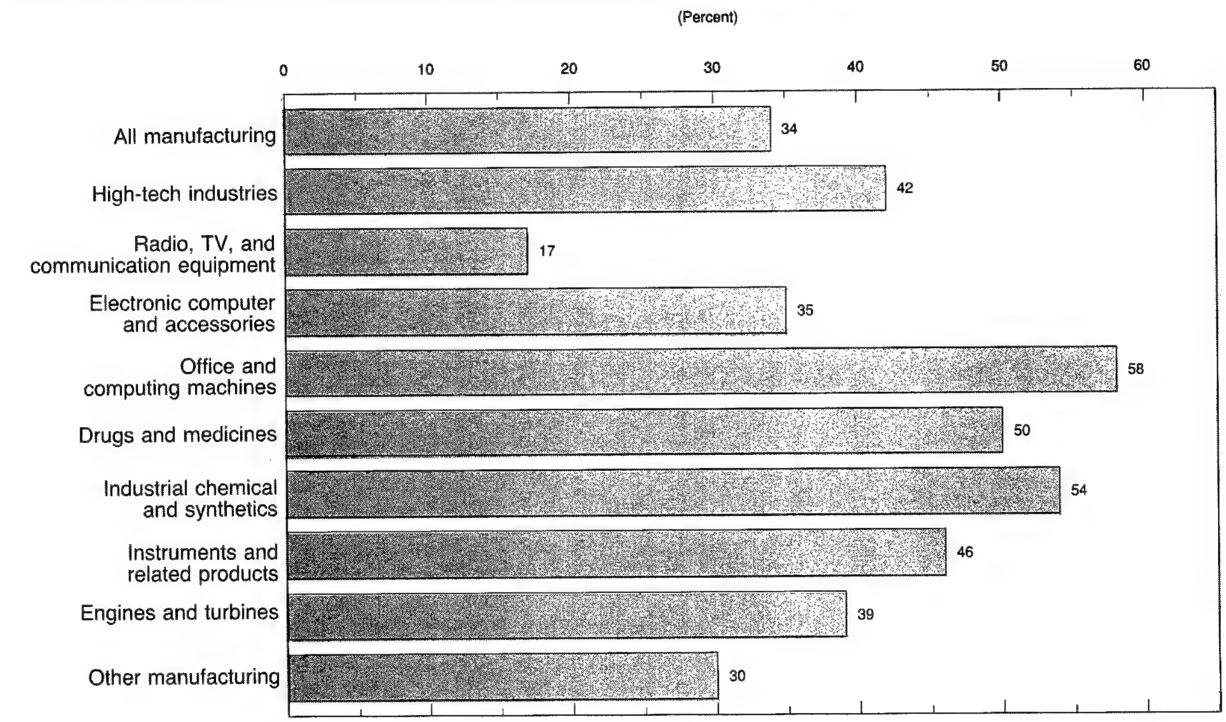
U.S. Direct Investment by High-Tech Multinationals. Establishing foreign affiliates provides U.S. firms with a means by which to break into a new market or improve their position in an existing market. Foreign affiliates also provide a mechanism to circumvent certain barriers erected to limit foreign competition. The data for 1986 suggest that high-tech manufacturing firms maintain a significantly higher portion of their assets in foreign affiliates than do other U.S. manufacturers. Assets of foreign affiliates for high-tech manufacturers accounted for nearly 42 percent of the parents' total assets, compared with 30 percent of total assets held abroad by non-high-tech manufacturers. (See figure 7-7 and appendix table 7-18.) U.S. parent firms operating in three high-tech fields—office and computing machines, drugs and medicines, and industrial chemicals—had assets in foreign affiliates representing over 50 percent of total assets.

The locations of the foreign affiliates set up by these high-technology firms suggest a bias associated with different products. U.S. multinationals' foreign investments in affiliated companies generally are heavily concentrated in Europe.[20] U.S. high-tech multinationals had 47 percent of their total assets in European foreign affiliates, compared with 42 percent for non-high-tech multinationals. (See figure 7-8 and appendix table 7-17.)

Affiliates established in Europe and Japan probably represent efforts by U.S. multinationals to expand sales in those markets. High-tech multinationals had 59 percent of

[20]Europe is defined as the 10 member countries of the European Community.

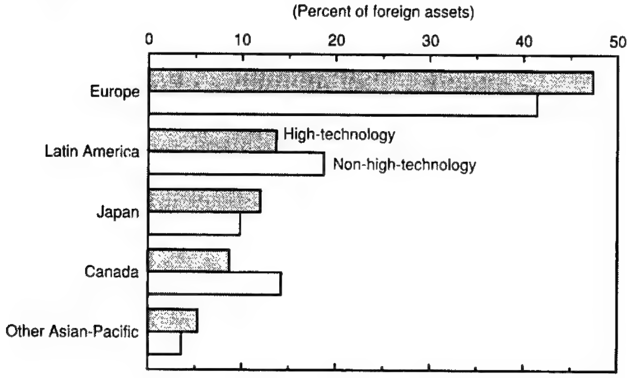
Figure 7-7.
Total foreign assets of U.S. corporations as a percentage of total assets: 1986



See appendix table 7-18.

Science & Engineering Indicators—1989

Figure 7-8.
Location of foreign affiliates of U.S. corporations: 1986



See appendix table 7-17. *Science & Engineering Indicators—1989*

their assets in foreign affiliates located in Europe and Japan (47 percent and 12 percent, respectively), while non-high-tech multinationals maintained 51 percent in Europe and Japan (41 percent and 10 percent, respectively). U.S. multinationals whose primary business involved computers (office and computing machines category) had close to 67 percent of their assets in Europe and Japan (52 percent and 15 percent, respectively), the highest for any high-technology field.

For the most part, foreign affiliate assets held by U.S. multinationals in the developing countries represent efforts to lower production costs and thereby increase competitiveness worldwide. Products manufactured in the developing countries are, for the most part, exported to developed countries, including the U.S. multinationals' home market. Many U.S. multinationals followed this path during the early 1980s when the appreciating dollar provided additional reason to move production facilities overseas. The experience did not always live up to expectations. Differences in culture, language, and business practices, as well as the distance from the U.S. headquarters, create additional costs that can erode much of the cost advantage that a firm expects to reap. With the dollar falling during 1987-88, there has even been some movement of production capability back to the United States, especially by firms that had not made the move offshore.

High-tech multinationals held 19 percent of their total assets in developing countries, compared with 22 percent for non-high-tech multinationals. Interestingly, U.S. multinationals whose primary activity involves the manufacture of computers had fewer assets tied up in developing countries than did U.S. manufacturers of other high-tech products. The rapidity with which technological changes occur in the computer field and the concomitant need for proximity to the innovative personnel may preclude offshore production except for the least sophisticated of computer products.

These data suggest that U.S. multinationals invest in foreign affiliates primarily to improve their market share in other developed countries. The suggestion is even stronger for U.S. multinationals in high-tech fields. Both the European Community and Japan represent large markets for high-technology goods; both protect these markets with trade barriers such as tariffs, "buy national" policies, and often unnecessary and discriminatory standards, testing, certifications, etc.[21] Foreign affiliates help U.S. firms circumvent the trade barriers that have impeded their competitiveness in the past. In general, the motivation for U.S. multinationals to establish foreign affiliates in lesser developed countries is to lower average production costs.

A recent U.S. International Trade Commission study appears to support these conclusions.[22] The commission found that:

- U.S. firms set up production facilities in Canada and Europe to facilitate sales in those markets.
- U.S. firms set up production facilities in Japan because they considered it a stable place to operate and because physical presence in Japan afforded firms better access to Japan's advanced technology.[23]
- In other East Asian countries, labor cost differentials and labor productivity were the incentives for U.S. firms' establishment of production facilities.

Patent Licenses, Royalties, and Technology Agreements

Although exporting and investing abroad are two very different strategies employed by U.S. companies to market their products in foreign countries, these strategies have an important element in common: any proprietary technology associated with the product being exported or manufactured by the foreign facility essentially remains controlled by the U.S. firm.[24]

Firms also may simply sell their rights to an invention, sell the right to market an invention, and/or provide technical information on an invention's production or use to

[21]See Office of the United States Trade Representative (1987), pp. 95-109 and 171-93.

[22]See U.S. ITC (1988a), pp. 5-1 to 5-7.

[23]Ibid. Most of the responding U.S. companies with production facilities in Japan were themselves subsidiaries of Japanese companies. The ITC study suggests that responses may be different if more respondents selecting this reason were not owned by Japanese multinationals.

[24]Both these channels for product sales provide opportunities for leakage of such proprietary know-how. The sale of high-tech products involves the export of so-called "embodied technology." The technology incorporated in the product often can be pirated through reverse engineering, thus permitting competitors to imitate and perhaps even improve upon the product.

U.S. investment in overseas production facilities also inadvertently transfers technology. First, the innovative firm sets up production of its technology-embodying product in the market, creating a transfer of technology analogous to that accompanying high-technology product export. Second, there is a transfer of "disembodied technology"—in setting up production facilities, the investing firm brings a panoply of formal and informal know-how associated with the technology's use and production. Through exposure to production facilities, competitors and potential competitors again reap benefits from the innovator's R&D.

another firm. The purchaser obtains a technological resource it may then use to its advantage—perhaps through production, modification, or marketing—and pays licensing fees and royalties to the original firm; these are frequently proportional to product sales.[25]

The inventing firm will often choose this marketing channel when it lacks the resources to exploit the technology fully (e.g., insufficient capital, raw materials, marketing expertise, etc.). Selling licenses to foreigners that permit the technology's reproduction, use, or resale typically take place when access to a market is made difficult because of tariffs, government restrictions, or lack of expertise about the market or customs that would facilitate the originating firm's entry. In return for the fee or royalty, the licensor sells not just information, but also partial control over the technology. The licensee gains knowledge or access to technology that would not otherwise be legally available.

To some extent, firms' receipts and payments for patents and technical knowledge represent a pure indicator of technological prowess. These sales—particularly between unaffiliated firms where prices are set through some market-related bargaining process—reflect only the exchange of technology and its market value at that point in time. These receipts and payments thus may be viewed as an "output" indicator providing a measure of the production and exchange of knowledge.

The United States is a net exporter of its technology via this mechanism. Royalties and licensing fees received from foreigners have been, on average, four times that paid out to foreigners by U.S. firms for access to their technology. (See appendix table 7-19.) In real terms, U.S. sales of technology through this channel were more or less constant during the 1970s, but have shown considerable growth during the 1980s.[26] U.S. receipts from such technology sales totaled $2.1 billion in 1987 (1982 prices), up from $1.4 billion in 1980.

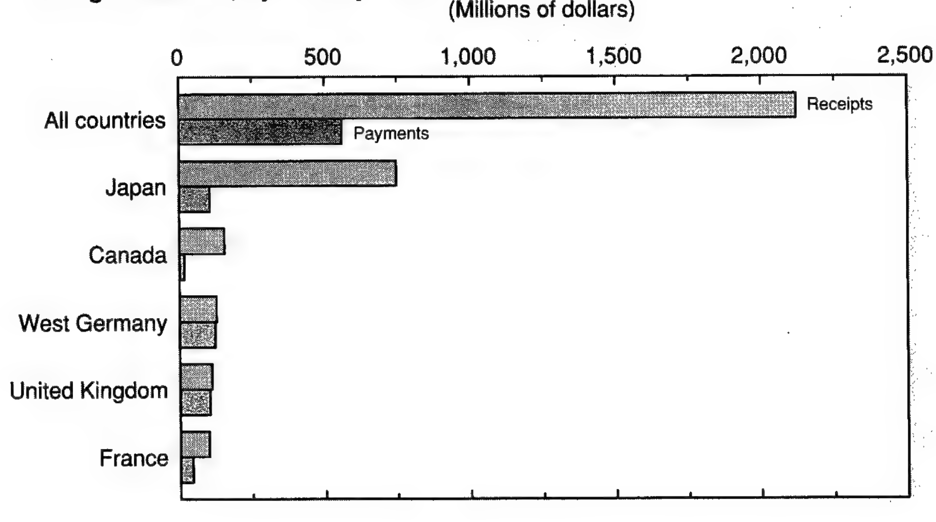
Japan is the largest consumer of U.S. technology sold in this manner. In 1987, Japan accounted for 41 percent of all such U.S. receipts, with Canada a distant second at 7 percent. Both these countries' payments for U.S. licenses were smaller in 1980—Japan accounted for 31 percent and Canada 5 percent that year. By contrast, purchases of U.S. technological know-how by other major industrialized countries—namely West Germany, the United Kingdom, and France—declined somewhat during the 1980s.

The United States has consistently maintained a trade surplus (i.e., receipts minus payments) in its sales of U.S. technology via this mechanism. (See figure 7-9.) In 1987, U.S. receipts were seven times its payments in licensing transactions entered into with Japan, eight times as large with Canada, and more than twice the payments to France. While the U.S. has maintained a surplus with West Germany and the United Kingdom, those surpluses have shrunk over the last couple of years and, as of 1987, were relatively small.

[25]Licensing fees are charges for the use of a patent or industrial process; royalties are payments for the use of copyrights or trademarks.

[26]Since receipts from royalties and fees paid by foreigners represent an export of U.S. goods, an export deflator developed by the Department of Commerce was used to discount the inflation-added value to these data. Appendix table 7-20 contains deflators for general exports and imports.

Figure 7-9.
U.S. receipts and payments of royalties and fees associated with unaffiliated foreign residents, by country: 1987



See appendix table 7-19.

Science & Engineering Indicators—1989

U.S. payments to technology sellers in the United Kingdom are larger than might be expected given the size of the British R&D endeavor. In 1985, United Kingdom R&D expenditures were less than one-third those of Japan, and about two-thirds the level in West Germany;[27] nonetheless, the United Kingdom received almost 30 percent of U.S. technology payments that year. (See appendix table 7-19.)

The total flows of receipts and payments of royalties and license fees are generated from new agreements and those made in previous periods that are still in force. Consequently, these data do not permit an analysis of new U.S. technology flows resulting from new agreements. While data on receipts and payments from new technology agreements are not available from U.S. sources, there are some data developed by the Government of Japan that disaggregate data for receipts and payments by new and existing agreements. (See appendix tables 7-21 and 7-22.) Since Japan is the dominant customer for U.S. technology sold through this channel and a major force in high-tech fields, these data provide additional insight about the relatively high level of U.S. technology sold via technology agreements.

During the 1980s, the United States entered into, on average, over 800 new agreements per year with Japan involving the exchange of technological know-how. There were 2.5 new agreements calling for U.S. exports to Japan of technological know-how for every 1 that represented a U.S. import of Japanese technology. Interestingly, during the 1970s, the exchange of technological know-how between the United States and Japan was more equitable; the ratio of new agreements representing U.S. exports of technological know-how compared with U.S. imports of Japanese know-how was approximately 1.2 to 1.

Japan apparently continues to consider the United States a fertile field from which to harvest new advances in technology. The surplus the United States enjoys in its trade in technological know-how with Japan does not rely solely on technological advances developed in the past, but is also supported by current innovative activity in the United States. While such sales contribute positively to the balance sheets of U.S. firms and the U.S. economy in the short term there remains considerable controversy about the long-term consequences of these technology sales.

PROSPECTS FOR U.S. TECHNOLOGY IN THE GLOBAL MARKETPLACE

Policy Developments

The role government plays in a country's ability to compete in the global marketplace is a subject of debate that converts few but engages a great many. Nevertheless, governments do intervene in the marketplace for a variety of reasons—many times in response to its philosophy, occasionally for social concerns, frequently in response to pressure from interested parties. This section explores changes in U.S. Government policy that affect U.S. commerce and its ability to compete in the global marketplace.

The year 1988 saw both significant changes in U.S. trade laws and progress in bilateral negotiations intended to provide new opportunities for U.S. trade. On the other hand, the European Community is preparing to enhance its competitive position in 1992 by further removing trade barriers among member countries. There are fears among some U.S. and other non-European manufacturers that they could find themselves at a comparative disadvantage in their efforts to sell to the European market unless they establish production facilities within Europe. But probably the most important policy development in 1988 for U.S. firms involved in international commerce is what was commonly referred to as the Trade Bill.

With President Reagan's signing into law of the Omnibus Trade and Competitiveness Act of 1988 on August 23, 1988, the U.S. Government attempted to "level the playing field"—i.e., to increase opportunities for U.S. firms overseas and equalize the terms of economic competition within the United States.

Several provisions of the act bear heavily on U.S. trade, including trade in high-tech products. Briefly, the act:

- Mandates the President to seek lower tariffs and eliminate nontariff barriers through both multilateral and bilateral negotiations.
- Required the U.S. to join 50 countries in the Harmonized Tariff on January 1, 1989; this will facilitate U.S. exporters' ability to market their products.
- Clarifies the Foreign Corrupt Practices Act to identify permissible foreign payments when doing business overseas.
- Empowers the President to restrict acquisitions of U.S. firms by foreigners when deemed important to national security.
- Requires that export controls on sensitive products and services be continuously reevaluated so that only those items truly important to safeguarding national security remain controlled.
- Implements new requirements for reciprocity in intellectual property, government procurement opportunities, and telecommunications trade.
- Expands the laws governing intellectual property rights to include process patents, and makes the laws less burdensome for those seeking government protection from infringing imports.
- Strengthens "unfair trade" statutes (e.g., antidumping and countervailing duty laws).
- Creates the Competitiveness Policy Council consisting of government, business, labor, and academic leaders with the mandate to identify and analyze problems and recommend strategies for improving U.S. productivity and competitiveness.
- Renames the National Bureau of Standards as the National Institute of Standards and Technology to

[27]See NSF (1987), p. 2.

reflect its broadened role. It is expected that the institute will become the lead Federal organization supporting industrial quality and competitiveness. The act directs the institute to involve itself in exchanges with foreign institutions to promote international exchanges of information on new technologies. The Advanced Technology Program is created under the institute's umbrella to function as a conduit to facilitate private sector access to the knowledge assembled by the institute and other Federal labs.

- Creates a 1-year National Advisory Commission on Superconductors consisting of members from government and the private sector to formulate a national strategy to ensure U.S. superconductor competitiveness.

The act's provisions go well beyond the areas summarized above. But potential gains for the U.S. economy are large in just two areas alone—the act's attention to export controls imposed on sensitive products and services, and to intellectual property rights.

A recent study conducted by the National Academy of Sciences assessed the impact of export controls on lost sales by U.S. firms, and suggested that these could exceed $9 billion dollars annually.[28] Most of the goods covered by export controls would be classified as high-technology products. While the act does not eliminate such controls, it does ease administrative burdens for firms involved in such trade, and it provides for ongoing removal of controlled products from the list of covered products as other countries make them available in the global marketplace. These changes will open markets previously closed to U.S. firms that trade in controlled products.

Another area of concern to U.S. high-tech firms addressed by the act is the need to strengthen intellectual property laws. A study by the U.S. International Trade Commission estimated that losses to U.S. firms as a result of violating U.S. intellectual property rights exceeded $11 billion dollars during 1986.[29] Again, a large percentage of the goods affected by these violations involve new products and processes in the high-technology area.

Almost 3 years in the making, the act is ambitious in its attempt to address so many areas of concern to U.S. business and labor communities. What impact it will ultimately have on U.S. competitiveness will be answered in the years to come.

Economic Factors

As a reference for the examination of U.S. competitiveness in high-technology fields, data on several important economic factors are presented to help explain potential shifts in technology flows. The factors selected—comparative exchange and inflation rates—are important factors, though they are not the only economic factors affecting U.S. international commerce. By tracking certain key economic factors, we may better understand the dynamics that influence future U.S. competitiveness.

As discussed earlier, consumers of high-technology products choose a particular supplier after carefully considering the product's ability to perform the required function, its quality, and its price. While high-tech products may tend to be less price sensitive[30] than other goods—especially those incorporating cutting-edge improvements or which are themselves state of the art—the bulk of products identified as high technology compete in a market composed of many competent sellers. Thus, sales of high-tech products will often turn on price. Two important elements that influence the price competitiveness of U.S. products are the *relative exchange rates* and *inflation rates* of the United States and of the countries that it competes against in the marketplace.

Increasingly, during 1980-85, U.S. firms were at a competitive disadvantage in the global marketplace due to a strong and strengthening dollar and an inflation rate higher than three of its major competitors—i.e., Japan, West Germany, and France. (See appendix tables 7-2 and 7-23.) During this period, the dollar appreciated close to 29 percent against the major industrialized countries.[31] The U.S. inflation rate was 3 times that in Japan and 1.5 times that in West Germany—these two countries alone accounted for 28 percent of global production of high-technology products. But after 1985, the prospect for improved price competitiveness for U.S. high-tech products stemming from changes in inflation and exchange rates predicts improved opportunities for U.S. high-technology products in the global marketplace.

In a DOC study analyzing the future price competitiveness of U.S. goods in world markets, several references to segments of the U.S. high-tech industry are mentioned.[32] Based on the level of U.S. exports of high-technology products in 1986 and the sources of competition for U.S. products in foreign markets, prospects for improved price competitiveness of U.S. high-tech products are strong both at home and in overseas markets. (See appendix table 7-25.) In the U.S. market, the estimated effect of currency and inflation changes projects an improved price-competitive position on some $32 billion dollars worth of high-tech products lost to foreign suppliers. Except for Canada, U.S. high-tech products should be more price competitive against the other major industrialized countries. Gains in the U.S. market at the expense of the lesser developed countries are predicted to be less favorable. According to this study, drugs and instrumentation products offer the greatest opportunities for increased U.S. high-tech product sales.[33]

---

[28]See National Academy of Sciences (1987), pp. 122 and 266.

[29]See U.S. ITC (1988b), pp. 4-5 and 4-6.

[30]High-tech products often can be unique, customized, or otherwise state of the art; sales of such goods are influenced less by price.

[31]Exchange rate comparison of U.S. dollar with the 13-Developed Country Average. See appendix table 7-2 for list of countries.

[32]Lawson and Young (1988), pp. 16-21.

[33]Opportunities for increased sales of U.S. high-tech products in the home market were considered "favorable" if the combined effect of recent price and currency changes has been to cause prices of goods from major foreign suppliers to increase much more rapidly—or to decrease much more slowly—relative to the average price of all other goods sold in the United States, including U.S. domestic and other imports.

In overseas markets, the DOC study foresees opportunities for market expansion in high-technology fields that could involve close to $27 billion in new sales. The dollar's decline should lead to gains in trade in markets in Europe and Japan and—to a lesser extent—in the East Asian NICs. Once again, pharmaceuticals offer the greatest prospects for capturing further market share overseas; U.S. chemical products are also projected to be more price competitive.[34]

[34]In this DOC study, recent price and currency changes in markets outside of the United States are said to be "favorable" to U.S. exports if their combined effect has been to cause U.S. prices to drop much more rapidly—or to increase much more slowly—relative to the average price of goods from all other sources.

Other economic factors project mixed signals for the immediate future. Gains in U.S. labor productivity lag behind those made by our major competitors and U.S. labor costs remain high. The savings rate in the United States remains well below that of our nearest competitors; this contributes to a cost of capital higher than that of our competitors.[35] The burdens of comparatively higher interest rates and labor costs, and a lower savings pool kept low by very high consumption habits, will continue to be a drag on the positive forces that have entered the competitiveness equation.

Chapter 8
Public Science Literacy and Attitudes Toward Science and Technology

CONTENTS

Public Science Literacy and Attitudes Toward Science and Technology

HIGHLIGHTS

- *The U.S. adult public has a very limited knowledge of physics and earth science.* Only 15 percent of American adults surveyed in 1988 could correctly answer all of seven simple questions posed on these topics. Three-quarters knew that light travels faster than sound, but only 43 percent knew that electrons are smaller than atoms, which is one of the most elementary facts of the atomic theory of matter. British respondents, who were asked the same questions at the same time, did a little more poorly on average. (See pp. 165-66.)

- *With regard to astronomy, there are also many misconceptions.* Twenty-one percent of Americans believe the sun goes around the earth, while another 7 percent do not know which goes around which. Only 45 percent know that the earth takes a year to go around the sun. British responses to these questions were correct even less often. A majority of Americans believes that the universe remains constant in size. (See pp. 166-67.)

- *The U.S. and British publics are very well aware of some basic health facts,* such as that sunlight causes skin cancer, and that stress and smoking contribute to heart disease. On the other hand, only about a quarter are aware that antibiotics cannot kill viruses. Many people in both countries are confused as to why they should do things like eat fiber and not eat food additives. Large numbers of Americans and Britons believe these actions help prevent heart disease. (See p. 167.)

- *Many Americans do not know or do not believe scientific accounts of early human history.* About 43 percent doubt that humans are descended from other animal species. Much smaller percentages in Britain, Japan, and the 12-country European Community reject the idea of human evolution. About 45 percent of Americans believe that early humans lived at the same time as dinosaurs. (See pp. 168-69.)

- *About 6 percent each of Americans and Britons say they act on their astrological forecasts.* Among young Americans, those aged 18 to 24, the level is 10 percent. Among those without a high school diploma, it is 11 percent. The same groups are also most likely to think that astrology is scientific. (See p. 170.)

- *The American public overwhelmingly believes that the world is better off because of science.* In both 1957 and 1988, 88 percent of respondents expressed this view. In both years, strong majorities believed the general proposition that science makes our lives healthier, easier, and more comfortable; and that science does not break down people's ideas of right and wrong. A parallel British survey asking some of the same questions received generally more negative assessments of the effects of science. (See pp. 170-71.)

- *However, in some respects, there is less public confidence in science in 1988 than in 1957.* For example, the number of Americans who believe that science can solve problems like crime and mental illness dropped from 47 percent to 23 percent. While only 23 percent believed in 1957 that science breaks down people's ideas of right and wrong, 33 percent said this in 1988. This drop in confidence occurred some time between 1957 and 1979. (See p. 171.)

- *Scientists generally are highly regarded by the public.* For many years, they have ranked second only to physicians on a list of professionals in which the American public has confidence. The scientific community has gained slightly in public confidence since the early 1970s, in comparison with some other institutions. (See pp. 172-73.)

- *The public believes that science and technology are good long-range investments.* About 80 percent believed—in 1985 and 1988—that the government should support scientific research even when it brings no immediate benefits. (See p. 174.)

- *However, the public gives higher priority to government funding in areas that have direct social application,* such as helping older people, improving education, reducing pollution, and improving health care. The British survey, addressing the situation in that country, found greater interest than in the United States in increasing government funding for scientific research. (See pp. 173-74.)

- *Most people consider the current level of government regulation of various aspects of science and technology to be adequate, if not excessive.* Substantial minorities, however, would like to see more regulation. Forty-two percent want more regulation of the use of chemical food additives, and 31 percent want more control over the construction of nuclear power plants. A majority is happy with the present level of regulation of basic scientific research. There was a decrease from 1985 to 1988 in the number that wanted to see more regulation of new pharmaceutical products, perhaps because of the AIDS problem. (See p. 174.)

- *A small majority supports research on animals if it produces information about human health problems.* In Britain, on the other hand, more people oppose than support animal research. Americans who oppose it tend to be female or

young. Support for animal research increases among the older age groups. (See p. 5.)

- *Between 1985 and 1988, there were numerous changes in public opinion about science and technology.* Positive changes included a higher overall assessment of the benefits of science as opposed to its harmful effects, and more optimistic assessments of the effect of science on daily life. Also, there was a large decrease in the percentage who regard scientists as dangerous. On the other side, there was more desire for the regulation of S&T, and more negative attitudes were expressed about the effects of technology on unemployment, animal research, the space program, and nuclear power. (See pp. 170-75.)

Science and technology (S&T) are undeniably of increasing importance to the life of the Nation. The other chapters of this report measure the various ways in which science and technology have been growing and changing, both as to levels of activity and as to outputs and products. This chapter is devoted to an assessment of how well the public understands, and how it regards, these developments. The National Science Board first sponsored the collection of data on the attitudes of the U.S. public toward science and technology in 1972. Since then, surveys of increasing scope and sophistication have been conducted for *Science & Engineering Indicators* approximately every 2 years. This chapter reports on the latest of these surveys, conducted in 1988.

The first part of this chapter examines the science literacy of the adult public. This is a new feature, reflecting the current interest in this subject shown by government and in the media. The second part of the chapter deals with public attitudes toward science and technology. Both the science literacy and the public attitudes data were collected in coordination with a parallel survey in Britain supported by the British government. As a result, an extensive comparison of U.S. and British science literacy and attitudes is presented here for the first time. This cooperation between countries follows a similar joint project between the United States and Japan, the results of which were reported in *Science & Engineering Indicators—1987*.

Another new feature of this chapter is the repetition of some survey questions first used in 1957 so that changes in attitudes since that time can be shown. In general, the chapter emphasizes the comparison of public attitudes measured in 1988 with those collected in earlier years using the same questions.

PUBLIC SCIENCE LITERACY

There is growing recognition in the industrialized world that public science literacy is an important component of long-term social and economic growth and of effective citizenship. In recent years, various studies in the United States and elsewhere have examined national science and mathematics education systems in an effort to improve them and thereby raise the level of public science literacy.[1]

Industrial economies will increasingly depend on advanced technologies, and new economic realities will demand an increasingly sophisticated workforce. This is illustrated by the pervasive impact of computers in service and manufacturing industries. The ability to use computers and similar technologies at work often depends on workers' level of scientific and technical literacy.

In addition, the growing impact of science and technology on our lives has brought an increasing number of S&T issues into the national agenda. Nuclear power, acid rain, and the "greenhouse effect," as well as medical advances and technological competitiveness, are increasingly subjects of media attention and political discussion in the United States and other industrialized nations. The issue of the safety of genetically engineered hormones in meat has triggered a trade dispute between the United States and the European Community. Similarly, trade disputes between the United States and Japan have arisen over computer chips, communications systems, and other high-tech products. The number of scientific and technical issues that demand public attention shows every sign of continuing to grow.

There is evidence that the proportion of citizens able to understand and follow these scientific and technical issues is low. Studies have found that relatively few Americans understand basic scientific terms or can make sense of arguments from experts on issues like nuclear power. Further, studies of recent high school graduates in the United States do not point to significant improvement from earlier generations.[2]

It would be valuable to have reliable measures of the level of public science literacy so that the scope of the problem could be assessed, trends measured, and comparison made with other industrialized countries. Techniques for making such measurements are still under development. Difficulties are complicated by the need to develop criteria that can be used internationally. This chapter reports on one of the first efforts to measure science literacy with the U.S. adult public and compare it with science literacy in another major industrialized nation, in this case Britain.[3]

For this purpose, surveys of the U.S. and British publics were performed simultaneously in June and July of 1988. The questionnaires were partly developed by mutual exchange of questions, so that responses received in the two

[1]See chapters 1 and 2.

[2]The source for the above is Miller (1989b). The most recent major study of the problem of public science literacy is AAAS (1989).

[3]This chapter speaks of Britain rather than the United Kingdom because the data discussed were collected in England, Scotland, and Wales, but not in Northern Ireland.

countries could be compared.[4, 5] Several dimensions of science literacy derived from these responses are treated separately in the following discussion.[6] Work is in progress to develop further the criteria for scientific and technological literacy and to extend the comparison to other countries.[7]

Acquisition of Information About Science and Technology

The U.S. public is strongly convinced of the need to be informed about science. Eighty-four percent disagreed with the idea that "It is not important for me to know about science in my daily life."[8] The public also believes that knowledge of science is possible: 72 percent agree that "If scientific knowledge is explained clearly, most people will be able to understand it."[9] Scientific knowledge thus is considered both desirable and attainable. This section considers what the public is actually doing to acquire it. In general, the public claims to have a surprisingly high amount of access to various sources of information about science and technology, and some responses may in fact be exaggerated.

Naturally, formal education is the way in which many persons acquire a certain level of scientific knowledge. Thirty percent of the U.S. respondents said they had taken at least one college-level course in biology, chemistry, or physics.[10] Most of these people, of course, did not become professional scientists or engineers, but many of them presumably retained some appreciation of science in later life, whatever careers they pursued.

Those who never studied science academically—and even those who once did but are not now actively involved in science—must depend on various public information sources to develop and update their scientific knowledge. For example, *museums* represent one important effort by science professionals to impart science information to the public. Of the 1988 sample, 26 percent reported that they had attended an S&T museum at least once in the past year, and 10 percent said they had done so more than once. In addition, 30 percent said they had gone at least once to a natural history museum, which is a very similar facility,[11] and 51 percent said they had gone to a zoo or aquarium. (By comparison, 33 percent reported that they had visited an art museum, and 68 percent reported visiting a public library.) Virtually identical responses were given in 1985. Attendance at S&T museums is highest in the 35- to 44-year-old age group; 34 percent of those in this age bracket have visited in the past year, while only 11 percent of those over 65 have. Attendance is also highest in the college-graduate group, where 50 percent went to an S&T museum in the past year, as opposed to 11 percent of those who had not finished high school.

Magazines and television are other media that help to convey science and technology information to the broad public. Television seems to be particularly effective, at least in terms of the number of people reached. In 1988, 84 percent of American respondents reported that they "regularly" or "occasionally" watch the program "Nova" or the National Geographic specials. This is up from 59 percent in 1979, 70 percent in 1983, and 71 percent in 1985.[12] When asked to list the magazines they read regularly or occasionally, 15 percent of American respondents named at least one S&T-related magazine.[13] The following discussion deals with the levels of knowledge about science and technology that the public has actually achieved from all these sources.

---

[4]The U.S. survey was performed in June and July 1988 with a representative sample of 2,041 adults aged 18 and over. Surveying was done by telephone at the Public Opinion Laboratory, Northern Illinois University. The response rate was 79 percent. With a sample of this size, results are uncertain by ± 3 percent or less at the 95-percent confidence level. With subsamples, the uncertainty will be greater. For simplicity, this chapter does not discuss the statistical significance of various differences in the data, but points out only differences regarded as significant. U.S. data discussed in this chapter, unless otherwise identified, are from Miller (forthcoming, 1989a). See also Miller (in press, 1990).

[5]The national survey of public understanding of science in Britain was performed in June and July 1988 by personal interviewing of 2,009 respondents representing England, Wales, and Scotland south of the Caledonian Canal. It was a joint project of the University of Oxford Department for External Studies and Social and Community Planning Research, funded by the Economic and Social Research Council. The British questionnaire was devised by John Durant, Geoffrey Evans, Patricia Prescott-Clarke, and Geoffrey Thomas, with advice and assistance from Donald Buzzelli, Barry Hedges, Roger Jowell, and Jon Miller. While the American data file has been reweighted to correct for any biases in the sample with respect to age, gender, race, or level of education, this has not been done with the British data. Unweighted samples tend to contain excessive numbers of educated respondents, so that slightly higher levels of science literacy are found in the British data than are justified. The British survey also offered "don't know" to the respondents as a possible reply to many questions, while the U.S. survey did not. In some cases, this may affect the interpretation of the results.

[6]No overall measure of national science literacy is developed in this chapter. However, a recent study using the present data found that 5.6 percent of the U.S. public can be considered scientifically literate. For the British public, also on the basis of these data, the corresponding figure is 7.1 percent. See Miller (1989b).

[7]This chapter deals with scientific literacy and has little to say about technological literacy. The National Science Foundation recognizes the importance of technological literacy, and efforts are planned to develop measures of it. However, at this stage, techniques for measuring science literacy are just beginning to be developed; even less is known about technological literacy. In any case, knowledge of science will certainly be a significant part of any measure of technological literacy.

[8]Another 14 percent agreed and 1 percent didn't answer. In Britain, not as many felt that knowledge of science is important. Only 57 percent disagreed with the statement, while 34 percent agreed, 8 percent neither agreed nor disagreed, and 1 percent gave no answer.

[9]Another 27 percent disagreed and 1 percent did not reply. In Britain, 73 percent agreed, 20 percent disagreed, 6 percent said "neither," and 1 percent did not reply. This is slightly more favorable to the possibility of public science education than is the American reply.

[10]Since the sample is reweighted to match the educational distribution of the whole public—along with other characteristics—this is probably a good representation of the extent of college-level science study among the entire U.S. adult population. For more detailed information on science and engineering education in the United States, see chapters 1 and 2.

[11]Forty-one percent reported attending either a science and technology museum or a natural history museum at least once in the past year.

[12]See Miller, Prewitt, and Pearson (1980); Miller (1983); and Miller (1985). In Britain, 84 percent reported watching one of the two most popular science-related television shows regularly or occasionally in 1988.

[13]In 1985, 16 percent gave that answer. Twelve percent of British respondents in 1988 stated that they read at least one magazine about "what is going on in science and technology."

Knowledge of Scientific Terms and Scientific Method

Scientific Terms. In their everyday reading, radio listening, or TV watching, people encounter news items that use more or less technical terms having to do with science and technology. Thus, an important component of being scientifically or technologically literate is the ability to understand a minimum number of technical terms when they are encountered. People often are able to understand these terms because of their formal education or from informal discussion or reading done later in life.

Previous studies have found that many people will say they know various technical terms when they really do not. Typically, less than half of those who say they have a clear understanding of a term can give a satisfactory definition of it if asked.[14] For example, 27 percent of American respondents claimed in 1985 that they had a clear idea of what a molecule is, though only 10 percent could give a satisfactory definition, even by generous standards. Similarly, only 8 percent could say how a telephone works, though 18 percent had claimed to understand its operation clearly. Thus, it is necessary to ask more specific questions in order to learn the actual level of public knowledge.

In 1988, American and British respondents were asked to give definitions for a set of terms. (See text table 8-1 and appendix table 8-1.)[15] Both American and British respondents were more familiar with computer software than with DNA.[16] In the case of DNA, more Americans than Britons appear to know what it is. On the other hand, very few Americans could give a definition of radiation that had some scientific content.[17] A larger number—a quarter of the U.S. sample—were able to give a less technical account of radiation, usually in terms of its effects or uses.[18] (See appendix table 8-1.)

Scientific Method. Another important aspect of being scientifically literate is having some knowledge of the methods and styles of thinking that characterize science. Advertising and the entertainment and news media often contain claims that some result has been established scientifically. The public should understand the habits of mind and procedures of science well enough to know what this claim means—and, perhaps, even to decide when it is likely to be true. In addition, scientific thinking is a thinking style that individuals often find valuable in their personal lives.

The question of what the public knows about the thinking or methods of science is a large one, but some information about it exists. (See text table 8-1.) Approximately 20 percent of the U.S. and British publics could explain what scientific study is. Three types of answers were regarded as correct. The first type had to do with the formulation and testing of hypotheses, leading to our best current understanding of nature. The second type had to do with performing experiments. The third type had to do with weighing all the evidence with an open mind.[19] More Britons than Americans gave correct answers. The first two answers were given in nearly equal numbers in both countries, but more Britons than Americans gave the third correct answer. (See appendix table 8-2.)

Text table 8-1. U.S. and British publics' knowledge of scientific terms and scientific method: 1988

	Percent answering correctly	
	U.S.	Britain
Terms		
Computer software	27	26
DNA	22	13
Radiation		
Scientific understanding	6	NA
Knows effects	25	NA
Scientific method	17	23
N =	2,041	2,009

NA = Not asked.

See appendix tables 8-1 and 8-2.

Science & Engineering Indicators—1989

Knowledge of Scientific Conclusions

A large part of being scientifically literate is knowing some of the conclusions that science has reached. Scientific research constantly produces new information of both theoretical and practical interest. The scientific community ought to be concerned about how much of this information has reached the public, both to expand people's intellectual horizons and to increase their ability to function in a technological society.

Physics and Earth Science. Public knowledge in this area was measured with seven questions, ranging from the very simple—e.g., whether hot air rises—to the more technical—e.g., how a laser works. (See text table 8-2.) There is a correspondingly wide variation in the numbers answering different questions correctly. While nearly everyone knew that hot air rises, only a minority knew that electrons are smaller than atoms or that lasers do not focus sound waves. The question about electrons is significant because it has to do with an elementary feature of the atomic theory

[14]See NSB (1987), pp. 143f.

[15]These results are based on coding of the open-ended survey questions at the Public Opinion Laboratory, Northern Illinois University, and at Social and Community Planning Research, London, England. Tests were made of intercoder reliability and of consistency of the categories into which responses were coded.

[16]In a 1987 survey, Japanese respondents also found computer software more familiar than DNA. See NSB (1987), appendix table 8-4.

[17]Acceptable answers referred to "energy" or "waves," for example.

[18]Answers in this group might refer to "bombs," "the sun," "can kill you," "cancer," "fallout," "power plants," or to medical uses.

[19]A fourth group of respondents answered in terms of looking at things carefully. The remaining responses were unclassifiable. (See appendix table 8-2.) Responses for the U.S. sample were coded at the Public Opinion Laboratory, Northern Illinois University, with tests of intercoder reliability.

Text table 8-2. U.S. and British publics' knowledge of facts of physics and earth science: 1988

	Percent answering correctly	
	U.S.	Britain
"Hot air rises."	97	97
"The oxygen we breathe comes from plants."	81	60
"The center of the earth is very hot."	80	86
"The continents on which we live have been moving their location for millions of years and will continue to move in the future."[1]	80	71
"Which travels faster, light or sound?"	76	75
"Electrons are smaller than atoms."	43	31
"Lasers work by focusing sound waves."	36	42
Correct responses to all seven questions	15	12
N =	2,041	2,009

[1]British wording: "The continents are moving slowly about on the surface of the earth."

See appendix table 8-3.

Science & Engineering Indicators—1989

Text table 8-3. U.S., British, and European Community publics' knowledge of facts regarding astronomy

	Percent answering correctly		
	U.S. (1988)	Britain (1988)	EC (1989)
"In the entire universe, there are thousands of planets like our own on which life could have developed."	67	NA	NA
"The universe began with a huge explosion."	54	64	NA
"Does the earth go around the sun, or does the sun go around the earth?"	73	63	83
"How long does it take for the earth to go around the sun?"[1]	45	34	63
N =	2,041	2,009	11,678

NA = Not asked.

[1]Question was asked only of those who said earth goes around sun. Percentages are based on total sample.

See appendix table 8-4.

Science & Engineering Indicators—1989

of matter. Those who do not know the relative sizes of electrons and atoms are unlikely to have much comprehension of the structure of matter.

It is often more useful to look at the numbers who answered a group of questions correctly rather than look at individual questions. Individual questions can be answered correctly by guessing,[20] but it is not likely that someone can guess all the correct answers to a set of questions. Only 15 percent of American respondents were able to answer all the listed questions correctly. (See text table 8-2.)

British respondents, who were asked the same set of questions, did a little worse. While they scored about the same as Americans on several questions, they did relatively poorly on the questions about oxygen coming from plants and electrons being smaller than atoms; overall, only 12 percent answered all the questions correctly.[21]

Astronomy. Some disappointing results were also obtained regarding public knowledge about astronomy. (See text table 8-3.) While most people knew that the earth moves around the sun, 21 percent of American respondents thought the sun moved around the earth and 7 percent had no answer. (See appendix table 8-4.) Even more British respondents answered incorrectly. In both countries, about 19 percent of respondents knew that the earth goes around the sun, but thought that this motion takes one day or one month; another 8 percent to 10 percent knew the earth goes around the sun, but did not know how long it takes.

The same two questions were asked in a 1989 survey of the 12 countries of the European Community.[22] In the European Community as a whole, the percentage that knew that the earth goes around the sun was higher than in the U.S. and British surveys. Only 11 percent thought the sun goes around the earth. (See text table 8-3 and appendix table 8-4.)

The question about whether the universe began with a huge explosion (the "Big Bang") was answered correctly by a majority in both the United States and Britain. (See text table 8-3.) The U.S. response was characterized by a large percentage saying that was "definitely true," while another large percentage had no answer. (See appendix table 8-4.)

A related survey in 1986 studied the cosmological beliefs of Americans more deeply.[23] Fifty-five percent understood that the sun is a star like millions of others; 37 percent said that the sun will eventually burn out, thus showing an

[20]Thus, the percentage of the public that actually knows some item of scientific information will be lower than reported here in many cases.

[21]Many of the items on text table 8-2 and later tables were developed by the Oxford University/Social and Community Planning Research team as part of the "Oxford Scientific Knowledge Scale."

[22]Interviewing was done in March and April 1989 by survey institutes in the individual countries, with coordination by the Faits et Opinions organization in Paris. Sample sizes were about 1,000 in each country—except for the United Kingdom (1,276) and Luxembourg (303)—for a total sample size of 11,678. To estimate the average for the entire European Community, responses from the individual countries were weighted according to national population counts of persons 15 years of age or older. See CEC (1989).

[23]Lightman and Miller (1989).

understanding of the impermanent nature of stars. The large numbers who believe in unidentified flying objects from other civilizations suggest a failure to understand the cosmic scale of distances and the consequent time it would take to travel from another star system to ours.[24]

An understanding of the Big Bang theory would lead to the conclusion that the universe is getting bigger, but only 24 percent of American adults gave that response.[25] About 59 percent said the universe is remaining constant in size. About 19 percent stated, in response to another question, that they would be troubled to learn that the universe is expanding.

The most important characteristic of respondents in predicting their cosmological understanding was education. Other significant characteristics, in order of importance, were:

- Gender (men tended to have more understanding),
- Age (the 30- to 49-year-old age group had more cosmological understanding than younger or older groups), and
- Church membership (nonmembers had more understanding).[26]

Probability. An important dimension of science literacy is mathematical literacy, the ability to comprehend magnitudes and make simple estimations. One aspect of mathematical facility is comprehending statements about probability. The U.S. and British publics did relatively well in this area. (See text table 8-4.) The question asked for the meaning of the statement that a couple has a "one in four chance" of having a child who will inherit a certain illness. Respondents were offered four possible interpretations of that statement, of which only one was correct.

Most respondents were able to recognize and reject the wrong interpretations and endorse the right one. (See text table 8-4.) Americans did better than the British in rejecting the wrong responses, but they also rejected the right response more frequently—23 percent rejected option c. (See appendix table 8-5.) As a result, more Britons than Americans got all four questions right, though more Americans got three right.

Health. Some items of scientific knowledge are not only of intellectual interest, but can also affect the way people behave. This is especially true for information about health. When American and British respondents were asked a set of health questions, their responses were very similar. (See text table 8-5.) There was a very high level of recognition that sunlight can cause skin cancer and that cigarette smoking causes lung cancer. A majority knew that radioactive milk cannot be made safe by boiling it.[27] However, only a small minority knew that antibiotics cannot kill viruses. This lack of information could be important to someone who is being treated for influenza, or to someone who expects a cancer cure in the near future.

Text table 8-4. U.S. and British publics' understanding of probability: 1988

	Percent answering correctly	
	U.S.	Britain
"Now, think about this situation. A doctor tells a couple that their genetic makeup means that they've got a one in four chance of having a child with an inherited illness."		
a. "Does this mean that if they have only three children, none will have the illness?" ...	87	84
b. "Does this mean that if their first child has the illness, the next three will not?"	86	80
c. "Does this mean that each of the couple's children has the same risk of suffering from the illness?"	72	82
d. "Does this mean that if their first three children are healthy, the fourth will have the illness?"	84	80
Correct responses to all four questions	57	66
N =	2,041	2,009

See appendix table 8-5.

Science & Engineering Indicators—1989

American and British respondents were also asked whether certain things contribute to heart disease. (See text table 8-5.) Almost all recognized that stress, smoking, not exercising, and eating animal fat do contribute. However, there was confusion about four other possible causes: not eating fresh fruit, lack of vitamins, not eating much fiber, and eating food with additives. In the first three cases, roughly as many people thought they caused heart disease as thought they did not. (See appendix table 8-6.) There was especially strong feeling that food additives can contribute to heart disease. It is possible that the public has absorbed a set of rules about good health habits (e.g., eat vitamins, don't eat fat) without knowing exactly which sicknesses these rules are intended to prevent.

Only 7 percent of American respondents, and 9 percent of the British, knew exactly which items do and do not cause heart disease. Responses from the two countries were very similar, except that there may be less concern in Britain about the effect of eating animal fat.[28]

[24]In 1985, 43 percent of American respondents said that "It is likely that some of the unidentified flying objects that have been reported are really space vehicles from other civilizations." See NSB (1987), p. 154. In 1988, a question that was similar but encouraged more "don't know" responses received 25 percent affirmative answers and 32 percent "don't know."

[25]Lightman and Miller (1989).

[26]These effects are calculated independently, so that any difference in education between the genders, for example, is corrected for.

[27]According to news stories, this was a practical issue for some Soviet citizens immediately after the Chernobyl accident.

[28]U.S. and British respondents were also asked which is the most serious cause of heart disease in their country today. The three most frequently mentioned items in the U.S. were smoking (38 percent), eating animal fat (25 percent), and stress (18 percent). In Britain, this order was somewhat reversed, as respondents reported smoking (41 percent), stress (27 percent), and eating animal fat (20 percent).

Text table 8-5. U.S. and British publics' knowledge about health: 1988

	Percent answering correctly	
	U.S.	Britain
"Sunlight can cause skin cancer."	97	94
"Cigarette smoking causes lung cancer."	96	NA
"Radioactive milk can be made safe by boiling it."	64	65
"Antibiotics kill viruses as well as bacteria."	25	28
Items contributing to heart disease		
Stress	96	95
Smoking	95	93
Not getting much exercise	95	91
Eating a lot of animal fat	94	87
Eating very little fresh fruit	44	47
Lack of vitamins	43	39
Eating very little fiber	41	45
Eating food with a lot of additives	25	29
Correct response on all eight items	7	9
N =	2,041	2,009

NA = Not asked.

See appendix table 8-6.

Science & Engineering Indicators—1989

Text table 8-6. Beliefs of U.S., British, and European Community publics regarding human origins

	Percent answering correctly		
	U.S. (1988)	Britain (1988)	EC (1989)
"Human beings as we know them today developed from earlier species of animals."[1]	46	79	62
"The earliest humans lived at the same time as dinosaurs."	37	46	47
N =	2,041	2,009	11,678

NA = Not asked.

[1]British response includes both "definitely true" and "probably true."

See appendix table 8-7.

Science & Engineering Indicators—1989

Human Origins. Quite a different sort of scientific information has to do with the origins of the human species. This issue is not only connected with scientific literacy, but also with antiscientific beliefs, which are discussed in the next section of this chapter. Nearly half of Americans believe that the human species is descended from earlier animals, while the percentage of British who believe this is much higher.[29] (See text table 8-6.) Nearly as many Americans reject human evolution (43 percent) as accept it. (See appendix table 8-7.) In Britain, as well as in Japan, there is no group of comparable size that opposes the idea of human evolution.[30]

The same question was asked in all 12 countries of the European Community in 1989. (See text table 8-6 and appendix table 8-7.) For the Community as a whole, there was a higher percentage answering correctly and a lower percentage answering incorrectly (only 24 percent) than in the United States. No European Community country had as large a minority opposed to human evolution as the United States has. According to preliminary data, the highest levels of rejection of evolution in the European Community were in The Netherlands (35 percent) and in Ireland (32 percent).

American and British respondents were also asked whether early humans lived at the same time as the dinosaurs. (See text table 8-6.) More Americans gave the incorrect answer than the correct one to this question. (See appendix table 8-7.) This may be due to the frequent depiction of humans and dinosaurs together in popular comics and films, like the Flintstones.

Interestingly, 48 percent of those Americans who believed in human evolution mistakenly believed that humans lived at the same time as dinosaurs. About as many (44 percent) of those who did *not* believe in evolution similarly believed humans and dinosaurs shared the earth for a time. Many people do not seem to recognize the long periods of time and the relatively late appearance of humans that the theory of evolution involves. This is true equally of those who accept evolution and of those who do not. In all, only 18 percent of American respondents both believed in human evolution and knew that humans and dinosaurs did not coexist.

More British than American respondents knew that humans did not live at the same time as dinosaurs. (See text table 8-6.) In the case of the British, 33 percent of those who believed in human evolution believed that humans lived at the time of the dinosaurs, while 30 percent of those who did not believe in evolution believed that humans and dinosaurs coexisted. Again, there is little connection between the responses to the two questions. About 38 percent of the British believed that human evolution is "definitely true" or "probably true" and also knew that humans did not live in the time of the dinosaurs.

In the United States, human evolution is accepted more often:

- By males than by females—52 percent versus 40 percent,
- By younger people (those aged 18 to 24) than by those 65 and older—54 percent versus 37 percent, and

[29]The British question allowed both "definitely true" and "probably true" as answers; the U.S. question did not. This may have caused a small increase in the relative numbers of Britons giving a positive answer, but there is still not nearly the same percentage of Britons as Americans giving a negative answer to the evolution question. (See appendix table 8-7.)

[30]For Japanese attitudes on this subject, see NSB (1987), pp. 153-55.

- By the more educated (college graduates) than by the less educated (those who did not finish high school)—63 percent versus 41 percent.

Scientific and Other World Pictures

Characteristics of Those Who Accept/Reject Scientific Conclusions. A recent analysis of the present set of U.S. and British data looked for the characteristics of those who accept or reject scientific conclusions in the areas of cosmology and evolutionary theory.[31] Reviewing the data discussed above, the study found that more Britons than Americans accept the Big Bang theory of the origin of the universe—64 percent versus 54 percent. (See text table 8-3.) It also found a very large difference in the number of Britons and Americans who accept human evolution—79 percent versus 46 percent. (See text table 8-6.)

The responses to these two questions were analyzed in terms of the responses to two others: (1) whether humans existed at the same time as dinosaurs (see text table 8-6), and (2) whether we depend too much on science and not enough on faith (see text table 8-10).

In both countries, a respondent's acceptance of human evolution is strongly associated with his or her acceptance of the Big Bang. Those who believed that we should depend more on faith were especially likely to reject human evolution; they were somewhat less likely to reject the Big Bang. The connection between reliance on faith and rejection of human evolution was particularly strong in the United States.

Further analysis found that the British responses to the Big Bang question could be explained entirely in terms of the respondents' levels of scientific knowledge—i.e., no effect was due to respondent education or religious belief. In the case of human evolution, however, both scientific knowledge and religious belief emerged as significant explanatory variables. Comparable data are not available for the United States.[32]

Limits of Scientific Method. While the U.S. public has considerable respect for science, it clearly has other interests. Many people feel that science is a limited field of study and that many important areas of life cannot be understood in scientific terms. For example, a majority of Americans believes that scientists will never be able to understand the workings of the human mind as well as they understand the physical world, and a large majority believes that there are good ways of treating sickness that medical science does not recognize.[33]

The general question of what things cannot be studied scientifically was asked of the U.S. public in 1957 and 1988. (See text table 8-7.) In 1988, a majority believed that science can delve into anything. This is more than the number who gave that answer in 1957, but in that year there was an especially large number who had no opinion.

Text table 8-7. Public belief about the limits of the scientific approach: 1957 and 1988

	1988
	(Percent)
Science cannot study	
Some things, but cannot say what	6
Religion, God, faith	12
Human behavior, thought	6
Nature: remote parts, origin; disease	4
Values, humanities, literature	2
Spiritual, unknown	1
Other	1
Science can study anything	59
Don't know/no answer	8
	N = 2,041

	1957
Science cannot study	
Some things, but don't know what they are	13
Religion, faith, the Bible	5
Human behavior, thought	4
Spiritual realms and beings	2
Aesthetic things, art, beauty	1
Humanistic areas, history, philosophy	1
Other miscellaneous areas	3
Science can study anything	47
Don't know/no answer	26
	N = 1,919

1988: "Are there any things that cannot be studied scientifically?"
IF YES: "What are some things that cannot be studied scientifically?"

1957: "Are there any things that can't be studied scientifically?"

Note: Multiple answers were accepted in 1957.

SOURCES: Survey Research Center (1958); Miller (1989a).

Science & Engineering Indicators—1989

Of the respondents who thought that some things cannot be studied scientifically, few in either year could name anything specifically. The answers that were given tended to center on the spiritual or religious. Other answers broadly referred to human thought and values. For some respondents, human origins evidently fall into this human and religious area that is outside the scope of science.

Nonscientific Beliefs. Large portions of the public hold beliefs that are inconsistent with the scientific world picture. For example, 44 percent believed in 1985 that rocket launchings and other space activities have caused changes in our weather.[34] This is inconsistent with scientific knowledge about the causes of weather changes or the effect something as small as a rocket could have on the atmosphere. In 1988, 37 percent of Americans believed that some numbers are especially lucky for some people.[35]

[31] See Evans and Durant (1989); also Durant, Evans, and Thomas (1989).

[32] However, the 1985 survey of U.S. adult public attitudes toward science and technology (reported in NSB, 1987, chapter 8) found—among other things—that 14 percent of church members "strongly disagreed" with human evolution, while only 3 percent of nonmembers did so.

[33] See NSB (1987), p. 156.

[34] See NSB (1987), p. 154.

[35] In addition, 58 percent disagreed and 5 percent had no opinion.

Again, number mysticism in its various forms is incompatible with the kind of causality recognized by science.

Astrology offers an especially interesting alternative to the scientific world picture. Influences of a kind that science does not recognize, coming from various astral bodies, are supposed to affect the characters of individuals and what happens to them. Knowledge of these influences is supposed to help in predicting the future, somewhat in the way the laws of a given science are used in making predictions. Technical language, charts, and calculations are employed that have some resemblance to those employed in the sciences, especially astronomy.

Perhaps because of these similarities, a significant portion of the public has astrology somewhat confused with science. (See text table 8-8.) While not many consider astrology "very scientific," a large minority regards it as "sort of scientific"; 37 percent give one answer or the other. On the other hand, the number who consider astrology "not at all scientific" has increased since 1979. The scientific status of astrology is accepted more often by women than by men, by those in the youngest age group (18 to 24), and by those with the least education. (See appendix table 8-8.)

While 17 percent of Americans say they read their personal astrology reports "every day" or "quite often," the number who say they act on these reports is much smaller, in the range of 5 percent to 8 percent. (See text table 8-8.) However, in view of the social stigma sometimes attached to such practices as astrology, the actual frequency may be higher than reported here. The same variation with gender, age, and education is seen as with the question on whether astrology is scientific. (See appendix table 8-8.)

Text table 8-8. Public attitudes toward astrology

	1979	1985	1988
	—— Percent ——		
"Would you say that astrology is very scientific, sort of scientific, or not at all scientific?"			
Very	8	8	6
Sort of	34	31	31
Not at all	50	57	60
Don't know/no answer	9	4	3
"In your daily life, do you sometimes decide to do or not to do something because your astrological signs for the day are favorable or unfavorable?"			
Yes	5	8	6
No	95	88	94
Don't know/no answer	NA	4	0
N =	1,635	2,005	2,041

NA = Not asked.

See appendix table 8-8.

Science & Engineering Indicators—1989

Those respondents who said in 1988 that they act on their astrological forecasts were further asked what those actions were. Fewer than half gave an answer. Of the answers given, many had to do with being careful about traveling or going out. Not spending money was the subject mentioned next in frequency.

In some respects, the British public shows more support for astrology than does the U.S. public. While only 6 percent of Americans consider astrology very scientific, at least 12 percent of Britons do.[36] The readership of personal astrology reports is greater in Britain than in the United States.[37] The number of Britons who claim to take horoscopes "very seriously" or "seriously" is 6 percent; about that many Americans say they act on horoscopes.

Similarly, the number of Britons who say they are serious or very serious about practices like touching wood or not walking under ladders is about 18 percent. As suggested above, reports of this kind are likely to be understated.

PUBLIC ATTITUDES

It is valuable to know the level of public science and technology literacy, as discussed above, but it is also important to know the feelings the public has about science and technology. In a democratic society, decisionmakers need to be aware of the degree to which the public supports certain S&T-related policies. It is equally important for those professionally involved with S&T to know the areas in which they have much or little public support. This section discusses the attitudes of the U.S. public toward science in general, its attitudes toward scientists, and its attitudes regarding some specific areas of policy that concern science and technology. Where possible, comparisons are made with earlier U.S. data and with the data recently obtained in the parallel British survey.

Attitudes Toward Science in General

Questions about the public's overall approval or disapproval of science have been asked in national surveys at least since 1957. In that year, the National Association of Science Writers sponsored a major survey of public interest, attitudes, information acquisition, and information needs regarding science.[38] This survey was the benchmark for all later studies, since it was performed just before the launching of Sputnik and the consequent changes in American attitudes and policies regarding S&T.

One of the 1957 questions that asked about general public support for science was repeated in the 1988 survey. (See text table 8-9.) Interestingly, there was virtually no change between the two surveys in the high percentage of respondents who believed that the world is better off

[36]The British question asked respondents to place astrology on a 5-point scale, ranging from 1 for "not at all scientific" to 5 for "very scientific." Twelve percent scored astrology 5, and 14 percent scored it 4. Therefore, between 12 percent and 26 percent of Britons gave an answer equivalent to "very scientific" in the American version of the question.

[37]Sixty-three percent of Americans, but 72 percent of Britons, say they read horoscopes at least sometimes.

[38]See Survey Research Center (1958).

Text table 8-9. U.S. and British assessments of the benefits and harms due to science

United States	1957	1988
	– Percent –	
"All things considered, would you say that the world is better off or worse off because of science?"		
Better	88	88

Note: For variations in question wording, see appendix table 8-10.

See appendix table 8-10.

Science & Engineering Indicators—1989

because of science. This consistency remains despite a long time lapse and the many events involving S&T that have occurred in public life, such as technological accidents, increased awareness of environmental pollution, and new medical discoveries.

Of course, some attitudes have changed over the 31-year period. For example, the number of people who believe that science will solve social problems like crime and mental illness has dropped significantly. (See text table 8-9.) This may reflect a more realistic contemporary view of the powers of science, but the public still does not withhold its overall support. The same conclusion can be drawn from the responses to two other questions that compare the benefits with the harms due to science. (See appendix table 8-9.) During the 1972-88 period, there have been yearly fluctuations, but—overall—the public overwhelmingly believes that the benefits of science outweigh the harmful effects.

A similar, though not identical, question about the benefits of science was asked in the British survey. (See text table 8-9.) There are enough negative responses to suggest strongly that the British public is not as convinced of the benefits of science as is the American public.

Four other questions repeated from 1957 also reflect broad public feelings about science. (See text table 8-10.) Substantial majorities of Americans continue to believe that science is making our lives healthier, easier, and more comfortable (question a) and that science does not break down people's ideas of right and wrong (question c). In both cases, however, there was less support for science in 1988 than in 1957. Apparently, the more negative sentiments actually developed between 1957 and 1979. Additional data show that little change in the responses to these two questions is seen from 1979 to 1988. (See appendix table 8-10.)[39]

[39]Since appendix table 8-9 shows virtually no change in the level of public support for science in the 1970s, it seems fair to say that any decline in public support took place sometime between 1957 and 1972.

As for whether science makes our way of life change too fast (question b), and whether we depend too much on science and not enough on faith (question d), the numbers who reject these negative assessments may actually have increased slightly from 1957 to 1988. This would be a positive development in public opinion toward science.[40]

Britons are more likely than Americans to agree that science makes our way of life change too fast (question b); also, fewer Britons seem to agree that science makes our lives healthier, easier, and more comfortable (question a).[41] (See text table 8-10.) These results are consistent with those on text table 8-9, and reflect the fact that Americans express more positive overall assessments. In general, the support of science on the part of the U.S. public—when expressed in very broad terms—seems to have held up quite well since 1957, though dissenting opinions increased in some areas between 1957 and 1979.

Attitudes Toward Scientists

The public's broad feelings about scientists are also of interest. For example, when students are deciding whether to pursue a career in science, the general picture they or their parents have of scientists as persons may influence their choice. Also, the scientific community issues various kinds of information and/or warnings to the public in connection with health and diet, environmental pollution, energy sources, the need for funding different research facilities, etc. The public's acceptance of these communications can be affected by the level of confidence it has in scientists and its attitudes about them.

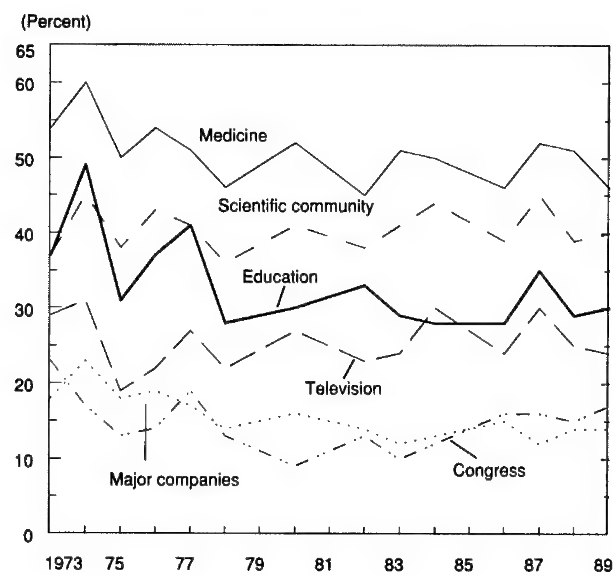
One measure of the public's view of scientists is the degree of confidence it has in leaders of the scientific community compared with those in other public institutions. (See figure 8-1.) This indicator is understood to represent the level of confidence in the institutions themselves.[42]

Since 1973, the scientific community has almost always ranked second only to medicine among the 13 institutions surveyed. (For the entire list of institutions, see appendix table 8-11.) This is a strong indication of support for science; more so since medicine is also a highly science-oriented profession. While there are distinct year-to-year fluctuations, the general trend is that the average level of confidence in all these institutions has decreased since the early 1970s. During this time, the scientific community has gained in relation to the average for all institutions. (See appendix text table 8-11.)

Other results allow current attitudes toward scientists to be compared with those expressed in 1957. (See text table 8-11.) A large majority agrees that most scientists want to work on things that will make life better for the average person, and a substantial majority disagrees with the statement that scientists are prying into things they ought to stay out of. For both statements, however, support for science was lower in 1988 than in 1957. This is consistent with the earlier results that show public support remaining high, but not as high as in 1957. Another question asked whether scientific researchers have a power that makes them dangerous. Again, a majority rejected the critical opinion in 1988. In 1985, however, a majority believed that scientists are dangerous.

These questions are useful for identifying trends in the general public feeling about scientists and also for identifying those groups within the public that are less supportive of science. For example, suspicion of the power of scientists was strongly dependent on level of education in 1988, with 52 percent of those lacking a high school diploma believing that scientists are dangerous. Similarly, there is a dependence on age: 48 percent of those over age 65 take that view. Those least likely to consider scientists dangerous are college-educated, aged 25 to 34, and male.

Figure 8-1.
Percentage of public expressing great confidence in people running selected institutions



See appendix table 8-11.

Science & Engineering Indicators—1989

---

[40]In early 1988, the National Opinion Research Center fielded two questions identical with those on text table 8-10. The responses—obtained by personal interview rather than by telephone and with a different sample—were very similar to those on the table and lend support to the quality of the present data. To question b, the responses were:
- Agree—40 percent,
- Disagree—58 percent, and
- Don't know/no answer—2 percent.

To question c, the responses were:
- Agree—32 percent,
- Disagree—65 percent, and
- Don't know/no answer—3 percent.

The sample size was 1,481. See NORC (1988), p. 366.

[41]Comparison is complicated by the existence of the middle response category in the British, but not the American, administration of these questions. The middle category does not affect the great difference between the U.S. and British responses on question b, and it probably does not on question a. In the case of question d, however, the large percentage responding "neither" on the British survey precludes comparison with the U.S. result.

[42]Smith (1981).

Science & Engineering Indicators—1989

Text table 8-12. U.S. public's view of dangerous powers possessed by scientists: 1988

Area mentioned	Percent mentioning
Nuclear	11
Biological	5
Weapons (nonnuclear)	4
Individual quirks	1
Chemicals	1
Environmental effects	1
Religion	1
Vague, no answer	13
Not asked[1]	62
N =	2,041

"When you think about scientific researchers who have powers that make them dangerous, what kinds of powers do you have in mind?"

[1]Question was asked only of those who had previously answered that scientific researchers have a power that makes them dangerous.

Note: A fuller statement of the responses comprised under these headings is given in appendix table 8-12.

SOURCE: Miller (1989a).

Science & Engineering Indicators—1989

Those 1988 respondents who considered scientists to have dangerous powers (38 percent of those interviewed) were further asked what these dangerous powers were. A large portion could not give a definite answer. (See text table 8-12.) Of the answers given, the most commonly mentioned area by far had to do with nuclear power, nuclear weapons, and radiation. There was also some mention of biological research and weapons in general.

Attitudes About Specific Policy Areas

A number of specific policy areas were selected for special study. These supplement the broad questions discussed above by moving away from science in general into matters of practical concern. One issue is whether people express the same level of support for science when specifics are involved rather than broad notions regarding science in general.

Priorities for Public Spending. One measure of public support for science is whether the public wishes the government to spend more for it. The U.S. public was asked about this in 1981 and again in 1988. (See text table 8-13.) Scientific research was put on a list of possible areas for public funding, in order to compare the public's interest in more science with its interest in other important matters that call for government funding. As the table shows, the public considers several other areas of public policy to require increased funding more urgently than does pure science. Some of these areas—like reducing pollution and improving health care—require the application of science. From 1981 to 1988, there was a substantial increase in public interest in improving education, reducing pollution, improving health care, and helping low-income persons. By contrast, the level of support for more pure science funding changed hardly at all over this period.

The space program, which is also S&T-related, has lower public support than scientific research as such. Public interest in supporting the space program also did not change much from 1981 to 1988. On the other hand, there was a large drop in the percentage of the public who wished to see more defense expenditures.[43]

More detailed information shows that of all the fields listed, the public is most neutral about science. (See appendix table 8-13.) Scientific research is the only policy area in which more people feel that the "right amount" is being spent, rather than either "too much" or "too little." Negative reactions are frequently expressed for space exploration and national defense, while most people want more spending in the other areas. The lukewarm reaction to more science spending may reflect the general feeling that science is a good thing, but not as appealing as other areas

[43]An experiment was run in the 1988 survey to see whether the wording of the question about defense had a significant effect on the response. (See text table 8-13.) The results show that there seems to be some effect: the public dislikes the notion of "weapons." In any case, the drop in interest in defense spending from 1981 to 1988 appears to be substantial regardless of wording.

Text table 8-13. U.S. and British public support for increased government spending on certain problems

Problem area	U.S. 1981	U.S. 1988	Britain 1988
	Percent		
Helping older people	73	76	80
Improving education	61	76	78
Reducing pollution	52	76	64
Improving health care	60	67	85
Helping low-income persons	44	55	72
Supporting scientific research	32	34	47
Exploring space	18	17	12
Developing and improving weapons for national defense	33	NA	NA
Improving national defense[1]	NA	17	NA
Developing weapons for national defense[1]	NA	11	7
N =	1,655	2,041	2,009

"We are faced with many problems in this country. I'm going to name some of these problems, and for each one, I'd like you to tell me if you think that the government is spending too little money on it, about the right amount, or too much."

NA = Not asked.

Note: Wording shown is for 1988 U.S. survey. Slightly different wording was used in 1981 and British survey.

[1]In 1988, the U.S. sample was divided, so that 999 answered this question with the first wording, and 1,042 answered it with the second wording.

SOURCES: Miller (1982), table 13; Miller (1989a); and Oxford (1988).

See appendix table 8-13.

Science & Engineering Indicators—1989

where the usefulness of spending is more direct and immediate.

A related question asked the American respondents "Even if it brings no immediate benefits, scientific research which advances the frontiers of knowledge is necessary and should be supported by the Federal Government." Eighty-one percent of the respondents agreed with this (79 percent in 1985); this shows overwhelming support for the idea that basic research is a suitable subject for Federal support.

British respondents were also asked about the areas in which they would like to see more or less government funding. (See text table 8-13.) They showed especially high interest in improving health care and helping older people and little interest in weapons for national defense. With regard to scientific research, they seem to have a greater desire for increased government funding than Americans have.

Government Regulation of Various Areas of Science and Technology. Another area in which the public can express its feeling about science and technology has to do with its desire to see more or less regulation of them. The desire for more regulation is an expression of some kind of fear or concern. Substantial minorities of Americans think that more regulation is needed in some areas. (See text table 8-14.) Basic scientific research does not arouse as much concern as chemical food additives or nuclear power plants, which affect the public directly. However, about a quarter of the public would like to see more regulation of basic research, and the number wishing to see such regulation seems to have increased since 1985. The only instance in which the desire for more regulation has decreased involves new pharmaceutical products. This may be related to the increased public interest in the development and dissemination of drugs to treat AIDS and similar diseases.

In most cases, a majority or plurality of respondents believes that the present level of regulation is about right. (See appendix table 8-14.) The exception is food additives; here, a plurality wants more regulation. Food additives and nuclear power plants are also the areas in which there are large percentages on the side of both more and less regulation.

In terms of demographics:

- More women than men want to increase regulation of food additives; more women also want to decrease it. (Men tend to be neutral.)
- Young people (18 to 24 years old) especially want less regulation of nuclear power. They also definitely oppose regulation of food additives, while older people are definitely in favor.
- The effect of education is quite straightforward: better-educated people are less in favor of regulating either food additives or nuclear plant construction.

Attitudes About the Effects of Computers and Automation on Employment. One of the most personal ways in which science and technology can affect members of the public is in terms of employment—whether they make more or fewer jobs available and how they affect the nature of people's jobs. Concerns about the effects of "automation" and/or "robots" on the nature and availability of

Text table 8-14. Public support for more regulation of various areas of science and technology
(Percent favoring more regulation)

Area	1985	1988
Use of chemical additives in foods	38	42
Construction of nuclear power plants	29	31
Conduct of genetic engineering research	20	25
Conduct of basic scientific research	17	23
Development of new pharmaceutical products	21	16
N =	2,005	2,041

"I'm going to read you a short list of activities and for each one I'd like for you to tell me whether you think that the present level of governmental regulation is too high, too low, or about right."

Don't know	NA	7	5	2
N =	1,630	2,005	2,041	2,009

"On balance, computers and factory automation will create more jobs than they will eliminate."

1983 wording: "On balance, computers will create . . ."

British wording: "More jobs will be created than lost as a result of computers and factory automation."

"Scientists should be allowed to do research that causes pain and injury to animals like dogs and chimpanzees if it produces new information about health problems."

1985 wording: "Studies (should be permitted) that cause pain and injury to animals like dogs and chimpanzees, but which produce new information about human disease or health problems."

British wording: ". . . about human health problems."

NA = Not asked.

[1]This option was offered to respondents in the British survey but not in the U.S. surveys.

SOURCES: Miller (1983); Miller (1985); Oxford (1988); Miller (1989a).

See appendix table 8-15.

Science & Engineering Indicators—1989

work have been widely expressed in many countries for many years.[44]

On the overall question of whether computers and automation will create more jobs than they will eliminate, Americans' opinions have fluctuated. (See text table 8-15.) In 1988, a small majority believed that more jobs will *not* be created. This is very similar to the response expressed in 1983, but not in 1985. The British public appears to be slightly more skeptical than the American public as to whether computers and automation will create jobs.

Attitudes About Research on Animals. Extensive controversy surrounds the issue of scientific experimentation on animals. In some well-known instances, public resistance has prevented or slowed the construction of laboratory facilities for such research. The U.S. and British publics were asked their opinion as to whether research that may harm animals should be allowed if it produces new information about human health problems. (See text table 8-15.) In this context, a small majority of the American public favors animal research, though not as many as in 1985. In Britain, the majority opposes animal research.

Although a majority of Americans favors animal research, a substantial minority is opposed. Further data help to show where in the public the support and opposition are located. (See appendix table 8-15.) Respondents were asked whether they strongly agreed, or only generally agreed, that animal research should be allowed; or whether they strongly, or only generally, opposed it. The results show that not many in any demographic group strongly support animal research, but that there are some groups in which it is strongly opposed.

Opposition is strongest among women and in the youngest age group (i.e., those from 18 to 24 years of age). Support for animal research clearly increases in older age groups. The effect of education is unusual: people with only a high school diploma are more opposed to animal research than those with more—or less—education.

Public Support of Space Exploration and Nuclear Power. American respondents were asked to assess these two areas in terms of their benefits versus the costs or risks they entail. In both cases, the level of public support was about equal to the level of opposition. (See text table 8-16.) Also, in both cases there was slightly less public support in 1988 than in the previous survey in 1985. Men favor both space exploration and nuclear power to a

Text table 8-16. Public assessment of space exploration and nuclear power

Area and assessment	1985	1988
	– Percent –

Science & Engineering Indicators—1989

[44]A more extensive discussion of public attitudes in this area, which compares U.S. with Japanese attitudes, can be found in NSB (1987), pp. 150-52.

greater extent than women do. (See appendix table 8-16.) Age does not have a strong effect on attitudes toward the space program, except that the oldest group (65 and older) is especially opposed. On the other hand, support for nuclear power increases among the older groups. Respondents with more education clearly give more endorsement to space exploration. With nuclear power, education is less significant, and there are large minorities in opposition even among college-educated respondents.

In 1985 and 1986, a study was made of the effect of the Challenger and Chernobyl accidents on public opinion. It showed that the Challenger accident in January 1986 had been followed by an immediate increase in public support for the *space program* in February 1986. By June 1986, that gain had slightly fallen off, when more information had been published about the causes of the accident and the Rogers Commission report had been issued.[45] More recent data show that by 1988, fewer people believed that the benefits of the space program exceed its costs than in November 1985, before the accident. (See appendix table 8-17.) Thus, in the case of the space program, the increased support at the time of the accident has dissipated, and the overall trend in support has been negative.

[45]See NSB (1987), pp. 162-65.

The Chernobyl accident in April 1986 had no immediate noticeable effect on Americans' assessment of the risk/benefit balance for *nuclear power*. Similar levels of support and opposition were seen in February 1986 and June 1986.[46] By July 1988, however, there had evidently been an erosion in public support for nuclear power. (See appendix table 8-17.) It is not clear how much of this is a delayed reaction to the Chernobyl accident.

The Challenger accident evidently produced an immediate shift in the levels of public support for *science in general*. From November 1985 to February 1986, there was an increase in those who felt that the benefits of scientific research exceed the harmful results. However, there was a sharp decrease in those who felt that the balance *strongly* favors beneficial results, with a corresponding increase in those who felt the balance is *only slightly* in favor of beneficial results. This shift persisted in June 1986, but by 1988, it was gone and the levels of support expressed in November 1985 had reappeared. (See appendix table 8-17.) In this case, the Challenger—and perhaps also the Chernobyl—accident had a transient effect on public opinion.

Appendix table 1-2. Levels of scientific proficiency used in the National Assessment of Educational Progress to classify student achievement scores

Level of classification	Definitions
Knows everyday science facts	Students at this level know some general scientific facts of the type that could be learned from everyday experiences. They can read simple graphs, match the distinguishing characteristics of animals, and predict the operation of familiar apparatus that work according to mechanical principles.
Understands simple scientific principles	Students at this level are developing some understanding of simple scientific principles, particularly in the life sciences. For example, they exhibit some rudimentary knowledge of the structure and function of plants and animals.
Applies basic scientific information	Students at this level can interpret data from simple tables and make inferences about the outcomes of experimental procedures. They exhibit knowledge and understanding of the life sciences, including a familiarity with some aspects of animal behavior and ecological relationships. These students also demonstrate some knowledge of basic information from the physical sciences.
Analyzes scientific procedures and data	Students at this level can evaluate the appropriateness of the design of an experiment. They have more detailed scientific knowledge and the skill to apply their knowledge in interpreting information from text and graphs. These students also exhibit a growing understanding of principles from the physical sciences.
Integrates specialized scientific information	Students at this level can infer relationships and draw conclusions using detailed scientific knowledge from the physical sciences, particularly chemistry. They also can apply basic principles of genetics and interpret the societal implications of research in this field.

Science & Engineering Indicators—1989

Appendix table 1-7. Levels of mathematics proficiency used in the National Assessment of Educational Progress to classify student achievement scores

Level of classification	Definitions
Simple arithmetic facts	Learners at this level know some basic addition and subtraction facts, and most can add two-digit numbers without regrouping. They recognize simple situations in which addition and subtraction apply. They also are developing rudimentary classification skills.
Beginning skills and understanding	Learners at this level have considerable understanding of two-digit numbers. They can add two-digit numbers but are still developing an ability to regroup in subtraction. They know some basic multiplication and division facts, recognize relations among coins, can read information from charts and graphs, and use simple measurement instruments. They are developing some reasoning skills.
Basic operations and beginning problem solving	Learners at this level have an initial understanding of the four basic operations. They are able to apply whole number addition and subtraction skills to one-step word problems and money situations. In multiplication, they can find the product of a two-digit number and a one-digit number. They can also compare information from graphs and charts and are developing an ability to analyze simple logical relations.
Moderately complex procedures and reasoning	Learners at this level are developing an understanding of number systems. They can compute with decimals, simple fractions, and commonly encountered percents. They can identify geometric figures, measure lengths and angles, and calculate areas of rectangles. These students are also able to interpret simple inequalities, evaluate formulas, and solve simple linear equations. They can find averages, make decisions on information drawn from graphs, and use logical reasoning to solve problems. They are developing the skills to operate with signed numbers, exponents, and square roots.
Multi-step problem solving and algebra	Learners at this level can apply a range of reasoning skills to solve multi-step problems. They can solve routine problems involving fractions and percentages, recognize properties of basic geometric figures, and work with exponents and square roots. They can solve a variety of two-step problems using variables, identify equivalent algebraic expressions, and solve linear equations and inequalities. They are developing an understanding of functions and coordinate systems.

Science & Engineering Indicators—1989

Appendix table 1-13. Levels of mathematics proficiency used in the International Assessment of Mathematics and Science to classify student achievement scores: 1988

Level of classification	Definitions
Perform simple addition and subtraction	Students at this level can add and subtract two-digit numbers without regrouping and solve simple number sentences involving these operations.
Use basic operations to solve simple problems	Students at this level can select appropriate basic operations (addition, subtraction, multiplication, and division) needed to solve simple one-step problems. They are capable of evaluating simple expressions by substitution and solving number sentences. They can locate numbers on a number line and understand the most basic concepts of logic, percent, estimation, and geometry.
Use intermediate level mathematics skills to solve two-step problems	Students at this level show growth in all mathematics topics in the assessment. They demonstrate an understanding of the concept of order, place value, and the meaning of remainder in division; they know some properties of odd and even numbers and of zero; and they can apply elementary concepts of ratio and proportion. They can use negative and decimal numbers; make simple conversions involving fractions, decimals, and percentages; and can compute averages. Students can use these skills to solve problems requiring two or more steps and can represent unknown quantities with expressions involving variables. Students can measure length, apply scales, identify geometric figures, calculate areas of rectangles, and are able to use information obtained from charts, graphs, and tables.
Understand measurement and geometry concepts and solve more complex problems	Students at this level know how to multiply fractions and decimals and are able to use a range of procedures to solve more complex problems. Students demonstrate an increased understanding of measurement and geometric concepts. They can measure angles found in simple figures, understand various characteristics of circles and triangles, can find perimeters and areas, and calculate and compare volumes of rectangular solids. Students are also able to recognize and extend number patterns.
Understand and apply more advanced mathematical concepts	Students at this level have the ability to deal with properties of the arithmetic mean and can use data from a complex table to solve problems. They demonstrate an increasing ability to apply school-based skills to out-of-school situations and problems.

Science & Engineering Indicators—1989

Appendix table 1-14. Levels of science proficiency used in the International Assessment of Mathematics and Science to classify student achievement scores: 1988

Level of classification	Definitions
Know everyday science facts	Students at this level know some general scientific facts of the type that can be learned from everyday experiences. For example, they exhibit some rudimentary knowledge concerning the environment and animals.
Understand and apply simple scientific principles	Students at this level exhibit a growing knowledge in the life sciences.
Use scientific procedures and analyze scientific data	Students at this level have a grasp of experimental procedures used in science, such as designing experiments, controlling variables, and using equipment. They can identify the best conclusions drawn from data on a graph and the best explanation for observed phenomena. Students also understand some concepts in a variety of science content areas.
Understand and apply intermediate scientific knowledge and principles	Students at this level demonstrate an understanding of intermediate scientific facts and principles and can apply this understanding in designing experiments and interpreting data. They also can interpret figures and diagrams used to convey scientific information. Students at this level can infer relationships and draw conclusions by applying facts and principles, particularly from the physical sciences.
Integrate scientific information and experimental evidence	Students at this level can interpret experimental data that involve several variables. They also can interrelate information represented in a variety of forms—text, graphs, figures, and diagrams. Students can make predictions based on data and observations and are aware of limitations of extrapolation. Students demonstrate a growing understanding of more advanced scientific knowledge and concepts, such as definitions of a calorie or the concept of chemical change.

[1]As projected in the mid scenario.

[2]The "other" engineering category includes a number of smaller fields that are combined in this report due to space limitations. None of these fields individually accounts for more than about 5 percent of the total engineering jobs.

[3]Base number is 0 or too small to estimate.

Notes: Detail may not add to total due to rounding. Percentages are calculated from unrounded data. Macroeconomic assumptions for the low, mid and high scenarios are described in appendix table 3-1a. The standard industrial classification codes are:

Goods-producing	
Durable goods	24, 25, 32-39
Nondurable goods	20-23, 26-31
Mining	10-14
Construction	15-17
Services-producing	
Communications/transportation/utilities	40-49
Trade	50-59
Financial services	60-67
Business and related services	70-79, 81, 83,89

SOURCE: NSF, Division of Science Resources Studies.

See figures 3-2, 3-3, 3-4, 3-5, 3-6, 3-17, 3-18, 3-19, 3-20, 3-21, and 3-22; and O-8 in Overview.

Science & Engineering Indicators—1989

Appendix table 3-1a. Summary statistics for macroeconomic scenarios: 1988-2000

Indicator	Low	Mid	High
	Macroeconomic scenarios		
	Average annual real growth		
	Percent		
GNP	1.8	2.3	2.8
Consumption	1.5	1.9	2.4
Business fixed investment	2.6	3.5	4.5
Exports	4.8	5.7	6.4
Imports	3.0	3.6	4.3
	Average annual growth		
	Percent		
Labor force	0.7	1.2	1.6
Productivity	1.3	1.4	1.6
Industrial production	2.2	2.9	3.5
	Average level		
	Percent		
Inflation (GNP deflator)	6.2	5.0	4.2
Unemployment	5.9	5.6	5.4

Notes: Growth rates for the projection period are compound annual growth rates calculated between the years 1988 and 2000. Level variables are averages for the years 1989 to 2000.

SOURCES: NSF and Data Resources (DRI).

Science & Engineering Indicators—1989

NA = Not available; S/E = science and engineering.

Notes: Detail may not add to total because of rounding. Total fields for 1988 were estimated based on the 1988 S/E employment rate for that year. Rates were not available by racial/ethnic group.

SOURCES: NSF, U.S. Scientists and Engineers: 1986; estimates and unpublished data.

See figure 3-9.

Science & Engineering Indicators—1989

Appendix table 3-12. Selected data on stock and flows of the S/E workforce, by occupational group or field of degree: 1986

	Total scientists and engineers		Natural scientists, engineers, and computer specialists		Social and behavioral scientists	
	Number	Percent	Number	Percent	Number	Percent
Status of 1985 S/E employed workers in 1986						
Total 1985	3,514	100.0	3,136	100.0	378	100.0
Employed in S/E	3,229	91.9	2,875	91.7	354	93.8
Deceased	28	0.8	26	0.8	3	0.7
Unemployed	11	0.3	17	0.5	[1]	[1]
Emigrated	15	0.4	12	0.4	4	1.0
Employed in non-S/E	132	3.8	119	3.8	13	3.5
Out of workforce	99	2.8	89	2.8	10	2.6
Source of 1986 S/E employed workers						
Total 1986	3,682	100.0	3,275	100.0	407	100.0
1985 S/E employed carryover to 1986	3,229	87.7	2,875	87.8	354	87.1
Total 1985 S/E graduates	227	6.2	196	6.0	31	7.6
U.S. citizens	210	5.7	180	5.5	30	7.3
Foreign citizens	17	0.5	16	0.5	1	0.3
Re-entrants to S/E employment	172	4.7	152	4.6	20	4.9
Direct immigration	30	0.8	28	0.9	1	0.3
Upgraded workers	24	24	0			
Workforce status of S/E graduates by broad field of study[2]						
Total	327	100.0	225	100.0	102	100.0
Employed in S/E	210	64.2	180	80.0	30	31.6
Employed in non-S/E	101	30.8	36	15.9	65	68.4
Out of workforce	10	3.0	5	2.2	5	5.3
Unemployed	6	2.0	4	2.0	2	2.1

S/E = Science and engineering.

[1]There was a net reduction of 6 in S/E unemployment.

[2]Excluding full-time graduate students.

Notes: Data rounded to nearest thousand and percentages are based on unrounded data. See text footnotes for definitions of methodology and caveats.

Engineers	104	182	189	137	183
Male	101	176	185	134	176
Female	4	6	3	2	8
Labor force	23,743,000	27,844,000	59,634,000	26,740,000	119,540,000

Notes: The number of scientists and engineers for France, West Germany, Japan, and the United Kingdom are estimates prepared by the U.S. Bureau of the Census based on published and unpublished census and survey data for the years shown. United Kingdom data excludes Northern Ireland. Figures refer to scientists and engineers employed in S/E jobs. Figures may not sum due to rounding. Data by gender for the United States are estimates. Labor force data are from the Organisation For Economic Co-operation and Development; thus, the number of scientists and engineers per 10,000 labor force differs from data published in the Bureau of the Census reports cited below.

SOURCES: Figures for West Germany, Japan, and the United Kingdom are from U.S. Bureau of the Census, Center for International Research, "Recent Data on Scientists and Engineers in Industrialized Countries" (Washington, DC, 1988). Data for France are from P.O. Way and E. Jamison, *Scientists and Engineers in Industrialized Countries* (Washington, DC: U.S. Bureau of the Census, Center for International Research, 1986). U.S. figures are from NSF.

See figure 3-24.

Science & Engineering Indicators—1989

Appendix table 3-14. Scientists and engineers in manufacturing for selected countries, by occupation group: most current years

Occupation	France (1982)	West Germany (1985)	Japan (1980)	United Kingdom (1981)	United States (1986)
			Percent		
Total scientists & engineers ...	100.0	100.0	100.0	100.0	100.0

Science & Engineering Indicators—1989

Appendix table 3-16. Scientists and engineers engaged in R&D for selected countries: 1965-87

	France	West Germany	Japan	United Kingdom	United States
	Thousands				
1965	42.8	61.0	117.6	49.9	494.6
1966	60.0	60.0	128.9	NA	521.1
1967	52.4	64.5	138.7	NA	534.4
1968	54.7	68.0	157.6	52.8	550.4
1969	57.2	74.9	157.1	NA	553.2
1970	58.5	82.5	172.0	NA	544.2
1971	60.1	90.2	194.3	NA	523.8
1972	61.2	96.0	198.1	76.7	515.3
1973	62.7	101.0	226.6	NA	514.8
1974	64.1	102.5	238.2	NA	520.8
1975	65.3	103.7	255.2	80.5	527.7
1976	67.0	104.5	260.2	NA	535.6
1977	68.0	111.0	272.0	NA	561.0
1978	70.9	113.9	273.1	87.7	587.0
1979	72.9	116.9	281.9	NA	614.8
1980	74.9	120.7	302.6	NA	651.7
1981	85.5	124.7	317.5	95.7	683.7
1982	90.1	127.7	329.7	NA	702.8
1983	92.7	130.8	342.2	94.1	722.9
1984	98.2	137.1	370.0	96.3	746.3
1985	102.3	143.6	381.3	98.0	772.5
1986	105.1	146.6	405.6	98.7	802.3
1987	108.2	151.5	418.3	NA	NA

NA = Not available.

Notes: Table includes all scientists and engineers engaged in R&D on a full-time basis except (1) Japan, whose data include persons primarily employed in R&D in the natural sciences and engineering; and (2) the United Kingdom, whose data include only the government and industry sectors. The figures for West Germany increased in 1979 in part because of increased coverage of small and medium enterprises not surveyed in 1977; data starting with 1979 were revised in 1988 using improved methodologies. The figures for France increased in 1981 in part due to a re-evaluation of university research efforts. Data are estimated by NSF for the following countries and years: France, 1986 and 1987; West Germany, 1978, 1980, 1982, 1984, 1986, and 1987; United Kingdom, 1984.

SOURCES: NSF; Organization for Economic Co-operation and Development; and national data.

See figure 3-27.

Science & Engineering Indicators—1989

Appendix table 3-17. Nonacademic scientists and engineers in selected countries, by age group: most current years

Age group	France (1982)	West Germany (1985)	Japan (1985)	United Kingdom (1981)	United States (1986)
	Percent				
Total	100.0	100.0	100.0	100.0	100.0
Under 35 years of age	30.0	30.3	48.5	47.3	32.9
35-54	58.0	56.0	44.9	41.0	49.0
Over 55	12.0	13.6	6.7	11.8	18.1

Notes: Figures for France, West Germany, Japan, and the United Kingdom are estimates prepared by the U.S. Bureau of the Census based on published and unpublished census and survey data for the years shown. United Kingdom data exclude Northern Ireland. Figures refer to scientists and engineers employed in S/E jobs. Figures may not sum because of rounding. U.S. data are for academic and nonacademic scientists and engineers, and exclude those respondents for whom no age was reported.

SOURCES: Figures for West Germany, Japan, and the United Kingdom are from U.S. Bureau of the Census, Center for International Research, "Recent Data on Scientists and Engineers in Industrialized Countries" (Washington, DC, 1988). Data for France are from P.O. Way and E. Jamison, *Scientists and Engineers in Industrialized Countries* (Washington, DC: U.S. Bureau of the Census, Center for International Research, 1986). U.S. figures are from NSF.

See figure 3-28.

Science & Engineering Indicators—1989

Appendix table 3-18. First university degrees for selected countries, by major field of study: 1986

	France[1]	West Germany	Japan	United Kingdom	United States
	Number of degrees				
All fields	52,728	63,866	376,260	72,000	1,074,785
Natural science and engineering	25,043	21,584	99,668	29,100	213,971
Natural science	11,321	10,766	12,814	17,500	122,170
Engineering	13,722	8,477	73,316	10,300	77,061
Agriculture	([2])	2,341	13,538	1,300	14,740
All others	27,685	42,282	276,592	42,900	860,814
	Percentage distribution among fields				
All fields	100.0	100.0	100.0	100.0	100.0
Natural science and engineering	47.5	33.8	26.5	40.4	19.9
Natural science	21.5	16.9	3.4	24.3	11.4
Engineering	26.0	13.3	19.5	14.3	7.2
Agriculture	([2])	3.7	3.6	1.8	1.4
All others	52.5	66.2	73.5	59.6	80.1
	As a proportion of the 22-year-old population				
All fields	6.1	5.9	22.6	7.4	25.9
Natural science and engineering	2.9	2.0	6.0	3.0	5.2
Natural science	1.3	1.0	0.8	1.8	2.9
Engineering	1.6	0.8	4.4	1.1	1.9
Agriculture	([2])	0.2	0.8	0.1	0.4
All others	3.2	3.9	16.6	4.4	20.7
22-year-old population	871,000	1,088,000	1,668,000	975,000	4,152,000

[1] Data for France are based on maitrise degrees and engineering degrees. French engineering degrees are equivalent to U.S. master's degrees.

[2] Included in natural sciences.

Note: Natural sciences include physical sciences, biological sciences, and mathematics.

SOURCES: U.S. data are from NSF; Japanese, Ministry of Education; West German, Statistisches Bundesamt; U.K., University Grants Committee; and French, Ministry of Education.

See figure O-7 in Overview.

NA = Not available.

Notes: Table includes all scientists and engineers engaged in R&D on a full-time equivalent basis except Japan, whose data include persons primarily employed in R&D in the natural sciences and engineering and all higher education science and engineering faculty. The United Kingdom data include only the government and industry sectors. The figures for West Germany increased in 1979 partially because of increased coverage of small medium enterprises not surveyed in 1977; starting with 1979, data were revised in 1988 using improved methodologies. The figures for France increased in 1981 in part due to a re-evaluation of university research efforts. Data are NSF estimates for the following countries and years: France, 1986 and 1987; West Germany, 1978, 1980, 1982, 1984 1986, and 1987; United Kingdom, 1984.

SOURCES: NSF; Organization for Economic Co-operation and Development; and national data.

See figure O-6 in Overview.

[1]Total funds used by Federal Government from Federal sources.

[2]Expenditures in federally funded research and development centers (FFRDC) administered by industry or nonprofit institutions are included in the totals for the respective sector.

[3]FFRDCs administered by universities and colleges and by university consortia.

[4]See appendix table 4-1 for GNP implicit price deflators used to convert current dollars to constant 1982 dollars. Current dollars will differ slightly from source document.

Note: Data based on annual reports by performers except for the nonprofit sector, for which data are estimated.

SOURCES: NSF, *National Patterns of R&D Resources: 1989,* NSF 89-308 (Washington, DC: NSF, 1989); and unpublished tabulations.

See figures 4-1 and 4-2, figure O-19 in Overview, and text table 4-1.

Appendix table 4-3. National expenditures for development, by performer and source: 1960-89

[1]Total funds used by Federal Government from Federal sources.

[2]Expenditures in federally funded research and development centers (FFRDC) administered by industry or nonprofit institutions are included in the totals for the respective sector.

[3]FFRDCs administered by universities and colleges and by university consortia.

[4]See appendix table 4-1 for GNP implicit price deflators used to convert current dollars to constant 1982 dollars. Current dollars will differ slightly from source document.

Note: Data based on annual reports by performers except for the nonprofit sector, for which data are estimated.

SOURCES: NSF, *National Patterns of R&D Resources: 1989*, NSF 89-308 (Washington, DC: NSF, 1989); and unpublished tabulations.

See figures 4-1 and 4-2 and O-4 in Overview.

Appendix table 4-5. National expenditures for basic research, by performer and source: 1960-89

[1]Total funds used by Federal Government from Federal sources.

[2]Expenditures in federally funded research and development centers (FFRDC) administered by industry or nonprofit institutions are included in the totals for the respective sector.

[3]FFRDCs administered by universities and colleges and by university consortia.

[4]See appendix table 4-1 for GNP implicit price deflators used to convert current dollars to constant 1982 dollars. Current dollars will differ slightly from source document.

Note: Data based on annual reports by performers except for the nonprofit sector, for which data are estimated.

SOURCES: NSF, *National Patterns of R&D Resources: 1989*, NSF 89-308 (Washington, DC: NSF, 1989); and unpublished tabulations.

See figures 4-1 and 4-2 and O-4 in Overview.

Appendix table 4-6. Federal obligations for R&D, by agency and character of work: 1980-89

NA = Not available.

[1]Conversions of foreign currencies to U.S. dollars are calculated with OECD purchasing power parity exchange rates. Constant 1982 dollars are based on U.S. Department of Commerce GNP implicit price deflators.

[2]French data are based on Gross Domestic Product (GDP); consequently, percentages may be slightly overstated compared to GNP.

SOURCES: NSF; Organisation for Economic Co-operation and Development (OECD); International Monetary Fund; and national sources.

See figures O-1 and O-2 in Overview.

NA = Not available.

[1]French data are based on gross domestic product; consequently, percentages may be slightly overstated compared to GNP.

[2]Foreign currency conversions to U.S. dollars are calculated with purchasing power parity exchange rates of the Organisation for Economic Co-operation and Development. See appendix table 4-1 for GNP implicit price deflators used to convert current dollars to constant 1982 dollars.

Note: After 1977, U.S. data are budget authority instead of budget obligations.

SOURCES: NSF; Organisation for Economic Co-operation and Development (OECD); International Monetary Fund; and national sources.

See figure O-3 in Overview.

Science & Engineering Indicators—1989

Appendix table 4-21. Basic research expenditures as a percentage of total R&D: 1975-86

	France	West Germany	Japan	United Kingdom	United States
	Percent				
1975	NA	26	15	14	13
1976	NA	25	18	13	13
1977	21	25	17	13	13
1978	NA	22	18	13	13
1979	21	20	17	13	13
1980	21	21	15	13	13
1981	21	21	15	12	13
1982	21	21	15	NA	13
1983	21	20	15	NA	13
1984	20	NA	14	NA	12
1985	20	18	13	NA	12
1986	20	NA	13	NA	12
1987	NA	NA	NA	NA	12

NA = Not available.

Notes: Data for basic research are somewhat less reliable than those for total R&D expenditures. Each percentage generally relates to the total current R&D expenditures; for countries other than the United States, this may include some general university funds. Data for France and the United Kingdom are estimated for certain years.

SOURCES: NSF; Organisation for Economic Co-operation and Development (OECD); and national sources.

See figure 4-7.

Science & Engineering Indicators—1989

Appendix table 4-22. R&D appropriations, by socioeconomic objective: 1987

Objective	France	West Germany	Japan	United Kingdom	United States
	Percent				
Total	100.0	100.0	100.0	100.0	100.0
Agriculture, forestry, and fishing	3.6	2.0	4.0	4.2	2.3
Industrial development	10.6	15.3	4.8	8.7	0.2
Energy	6.7	8.7	23.2	3.5	3.6
Infrastructure	3.2	1.9	1.8	1.5	1.8
Transport and telecommunications	(1)	(1)	1.4	0.4	1.6
Urban and rural planning	(1)	(1)	0.4	1.2	0.2
Environmental protection	0.4	3.3	0.5	1.0	0.5
Health	3.6	3.2	2.4	4.3	11.9
Social development and services	2.7	2.3	1.0	1.5	1.0
Earth and atmosphere	1.4	1.9	1.0	1.7	0.7
Advancement of knowledge	26.6	43.8	50.8	20.2	3.6
Advancement of research	14.7	12.3	7.3	4.6	3.6
General university funds	12.0	31.5	43.5	15.6	(2)
Civil space	5.9	4.9	6.1	2.7	6.0
Defense	34.1	12.5	4.5	50.3	68.6
Not elsewhere classified	1.0	0.1	—	0.3	—

[1]Not separately available but included in subtotal.

[2]The United States does not have an equivalent to Europe's and Japan's general university funds.

Notes: Percentages may not add to 100 because of rounding. Additionally, because of general university funds and slight differences in accounting practices, the distribution of government budgets among socioeconomic objectives may not completely reflect the actual distribution of government-funded research in particular fields. Japanese data are based on science and technology budget data, which include items other than R&D. Nevertheless, such items are a small proportion of the budget, and the data may still be used as an approximate indicator of relative government emphasis on R&D by objective.

SOURCES: NSF; Organisation for Economic Co-operation and Development (OECD); and national sources for Japan.

See figure 4-8.

Science & Engineering Indicators—1989

Appendix table 4-23. Academic and academically related research, by field and country: 1987

Field	United Kingdom	West Germany	France	The Netherlands	United States	Japan
	Millions of dollars					
Total	2,821	3,979	3,211	960	14,897	3,738
Engineering	447	492	359	109	1,963	809

[1]Percentage of total R&D provided by industry.

[2]Ranking is derived by sorting campuses receiving R&D funding into groups of 25 from highest to lowest funding. Dollars show range of total R&D expenditures per campus, for the 25 campuses.

[3]Data include only those campuses reporting that they received separate industrial R&D support.

[4]Data for industrial support were imputed.

[5]Data for industrial support were estimated.

[6]Includes campuses reporting no industrial support and campuses reporting industrial support data not available.

N.E.C. = Not elsewhere classified.

[1]Estimate is unstable.

Note: Estimates for the agricultural, biological, and environmental sciences are for 1983 and 1986. Estimates for all other fields are for 1982 and 1985. Data apply to instrument systems costing between $10,000 and $1 million. Data exclude instrument systems not yet in use (approximately 1,200 systems), and inactive/inoperable systems (approximately 9,300 systems). Detail may not add to total because of rounding. Data are adjusted for inflation both in terms of instrument prices and in weighting school responses based on their total R&D expenditures.

[1]These categories contain fewer than 20 individuals.

[2]The first row for each sector contains horizontal percentages. The next two rows are vertical percentages, showing the percentages of males and of females within each employment sector by racial/ethnnic group.

Notes: Researchers are counted if they said on their Survey of Doctorate Recipients form that their primary or secondary work activity was basic research. Hispanics are present in various racial groups; therefore, they are not separately added into the total.

Science & Engineering Indicators—1989

Appendix table 5-21. Proportion of doctoral researchers who remained employed in a sector, for selected time intervals between 1973 and 1987

	Elapsed time	Total[1]		4-year colleges and universities		Business/industry		Nonprofit		Federal Government	
		Male	Female	Male	Female	Male	Female	Male	Female	Male	Female
	years	Percent retained in same sector									
1973-75	2	91	86	94	90	95	83	65	59	80	77
1975-77	2	92	88	94	90	96	93	69	66	88	74
1977-79	2	91	86	92	88	95	91	73	65	88	74
1979-81	2	92	88	93	91	95	84	74	72	91	79
1981-83	2	92	85	93	88	94	88	62	61	92	78
1983-85	2	92	88	93	90	93	86	68	70	87	84
1985-87	2	92	87	94	89	91	88	76	64	88	80
Average	2	92	87	93	90	94	87	70	65	88	78
1973-77	4	87	82	90	87	91	78	54	45	74	67
1983-87	4	87	82	90	85	85	78	62	55	77	72
1973-83	10	81	71	85	76	86	59	40	48	67	58
1977-87	10	77	72	80	75	79	73	32	33	70	66
1973-87	14	74	66	79	71	77	47	31	33	56	60

[1]Total includes other sectors, such as hospitals/clinics and the military.

Notes: Data are for doctoral scientists and engineers whose primary or secondary work activity was nonacademic basic research or academic R&D during the initial year of an interval, and who also responded at the end of the interval. There were 15,000 matched respondents for 1973-75; 6,000 of them also responded in both 1973 and 1987. Partly because of changing sampling strategies, response rates over different time intervals are not readily compared. Percentages for women are unstable in some categories that have had low numbers of women, such as business/industry during the 1970s.

[1]See appendix table 5-24 for the subfields included in these fields.

Notes: When an article is written by researchers from more than one country, that article is prorated across the number of author institutions in each country. Thus, if a given article has authors from two institutions in France and from one institution in the United States, it is counted as two-thirds of a French article and one-third of a U.S. article. Detail may not add to total because of rounding.

Data for 1973-80 are based on the articles, notes, and reviews in over 2,100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information; 1981-86 data are based on over 3,200 journals on the 1981 Science Citation Index Corporate Tapes.

Notes: When an article is written by researchers from more than one country, that article is prorated across the number of author institutions in each country. Thus, if a given article has authors from two institutions in France and from one institution in the United States, it is counted as two-thirds of a French article and one-third of a U.S. article. Data are based on the articles, notes, and reviews in over 3,200 of the influential journals carried on the 1981 Science Citation Index Corporate Tapes.

Notes: Data for 1973-80 are based on the articles, notes, and reviews in over 2,100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information; 1981-86 data are based on over 3,200 journals on the 1981 Science Citation Index Corporate Tapes. Articles are attributed to a country if at least one author is from the country. Because of multiple counting of papers, adding together the numbers for different countries would lead to a larger count than the actual number of published papers.

See figure O-17 in Overview and text table 5-5.

Appendix table 5-29. International science and engineering coauthorship, by U.S. sector: 1981-86

Sector	1981	1982	1983	1984	1985	1986
	Percent of articles involving cross-national collaboration					
Academic institutions	7.7	8.0	8.6	9.3	9.7	10.2
Nonprofit institutions	5.7	6.3	6.9	7.5	8.0	8.7
FFRDCs	9.6	11.5	11.8	14.1	13.3	14.8
Federal and local government	6.0	6.6	7.4	7.9	8.3	8.6
Industry	5.5	6.5	6.5	7.0	7.9	7.9
	Number of articles involving cross-national collaboration					
Academic institutions	7,980	8,484	9,098	9,857	10,840	11,472
Nonprofit institutions	829	914	1,024	1,121	1,259	1,344
FFRDCs	614	714	756	829	928	1,031
Federal and local government	1,330	1,454	1,601	1,733	1,830	1,922
Industry	743	890	944	999	1,196	1,219
	Total articles					
Academic institutions	104,112	106,657	105,246	105,598	111,690	112,639
Nonprofit institutions	14,624	14,597	14,919	14,862	15,664	15,389
FFRDCs	6,393	6,186	6,417	5,884	6,952	6,981
Federal and local government	22,014	22,132	21,750	21,816	22,118	22,254
Industry	13,462	13,705	14,598	14,220	15,127	15,453

FFRDC = Federally funded research and development center.

Notes: Data are based on the articles, notes, and reviews in over 3,200 journals on the 1981 Science Citation Index Corporate Tapes. Articles with at least one author from the specified sector are counted in that sector. Thus, an article coauthored by two sectors will be counted twice, once for each sector. Therefore, the columns will add to a larger number of articles than the actual number published.

FFRDC = Federally funded research and development center.

Notes: Data for 1973 and 1976 are based on the articles, notes, and reviews in over 2,100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information; 1982-1986 data are based on over 3,200 journals on the 1981 Science Citation Index Corporate Tapes. An article is counted from a sector if one or more authors is from the sector. Partly because some articles have authors from more than two sectors, the "All sectors" total is slightly less than the sum of the four individual sector coauthorships.

Notes: Data are based on the articles, notes, and reviews in over 2100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information. Cited years were on a 2-year lag, 3-year rolling cycle after the year of the citing paper. For example, for the 1986 citing year, only papers published in 1982-84 were counted as cited papers.

[1] Also called "relative citation index," this measures the share of citations a country, sector, etc., gets relative to the share of the world's literature it produces.

Notes: Data are based on the articles, notes, and reviews in over 2,100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information. Citations are counted in a 2-year-lag, 3-year rolling cycle. For example, for citing year 1982, citations to publications in years 1978-80 are counted.

FFRDC = Federally funded research and development center.

Notes: Data are based on the articles, notes, and reviews in over 2,100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information. When an article is written by researchers from more than one sector, that article is prorated across the number of author institutions in each sector. Thus, if there are authors from two academic institutions and one FFRDC, the paper is counted as two-thirds of an academic paper and one-third of an FFRDC paper. Citations are counted in a 2-year-lag, 3-year rolling cycle. For example, for citing year 1982, citations to publications in years 1978-80 are counted.

	Percent of world papers in field[3]				
Field					
Engineering	100.0	41.5	50.6	7.9	0.0
Physics	100.0	1.0	2.4	32.5	64.1
Chemistry	100.0	0.7	2.8	27.8	68.7

[1]Papers are given the categories of the journals in which they appear; journals are categorized from more applied to more basic research content.

[2]Except for the "All" column, which has vertical percentage data, the columns show horizontal percentages, that is, the percentages of papers in each of the research categories, by field.

[3]Distribution of world publications was determined for 1973-79. Data for more recent years suggest a similar distribution.

Note: Citations in the citing year and all previous years (to 1973) were counted. Data are based on the articles, notes, and reviews in over 2100 of the influential journals carried on the 1973 Science Citation Index Corporate Tapes of the Institute for Scientific Information.

437 Semiconductor device manufacturing: process	68	1	3	5	6	8	10
358 Pictorial communication; television	59	3	3	2	3	8	9

[1]These data are the average number of patents per year over 5-year periods, where indicated. To get total patents during those periods, multiply the yearly average by 5. The total column shows actual numbers of patents awarded.

Note: Data are shown for the patent classes that accounted for 1 percent or more of total academic patenting activity by at least two of the following three measures: total patents 1971-88; total patents 1987; total patents 1988.

SOURCE: U.S. Department of Commerce, Patent and Trademark Office, special tabulations for NSF, 1989.

See text table 5-7.

Science and Engineering Indicators—1989

Appendix table 5-38. Patents for top 10 patenting universities, by patent class, summed for 1986-88[1]

Patent class and name[2]	All 10 schools (317)	MIT (63)	Univ of Calif (59)	Stanford Univ (54)	Univ of Minn (26)	Johns Hopkins (21)	Univ of Florida (21)	Univ of Wisc (20)	Caltech (18)	Univ of Texas (18)	Harvard Univ (17)
	University (number of patents awarded in 1988)										
	Number of patents, 1986-88										
Total, all classes	867	171	181	135	70	57	44	48	68	65	28
Total, classes below	586	115	134	112	44	31	22	36	28	43	21
435 Chemistry, molecular biology and microbiology	97	15	33	8	7	2	1	13	2	10	6
128 Surgery	64	7	17	11	5	10	6	2		6	
514 Drug, bioaffecting and body treating compositions	56	13	13	2	5	4	7	5		4	3
424 Drug, bioaffecting and body treating compositions	43	5	13	8	5		3	1	1	5	2
324 Electricity, measuring and testing	41	2	26	4	1	1		2	1	3	1

372 Coherent light generators	18	4	1	8					5		
604 Surgery	20	1			9	7				2	1
364 Electrical computers and data processing systems	19	2	3	6		3	2		2		1
437 Semiconductor device manufacturing: process	14	10		2	1				1		
250 Radiant energy	16		3	4		1		1	5	2	
530 Chemistry, peptides, lignins or reaction products	21	3	5	4						4	5
204 Chemistry, electrical and wave energy	16		5	1	2		2	1	1	3	1
436 Chemistry, analytical and immunological testing	15	3	5	2	1			2	1		
428 Stock material or miscellaneous articles	13	8	2	1		1		1			
427 Coating processes	11	8			2			1			
156 Adhesive bonding and miscellaneous chemical manufacture	10	7	1			1		1			
260 Chemistry, carbon compounds	8	2						6			
528 Synthetic resins-class 520	7	6	1								
062 Refrigeration	6				2					4	
556 Organic compounds-part of class 532-570	7	4			1				2		
310 Electrical generator or motor structure	5	4		1							

[1]The top 10 patenting schools in 1988 are used in this analysis. The 3-year period is used to partly smooth out year-to-year variability in the distribution of patent classes. A list of the top 10 patenting schools based on cumulative patents during the 3-year period would differ slightly from the list used here.

[2]A patent class is included if at least one of the top 10 patenting universities in 1988 received four or more patents in that class during 1986-88.

Note: Blank cells indicate zero patents.

NA = Not available.

[1]Break in series from previous year for which data shown.

[2]National estimate or projection adjusted by the Organisation for Economic Co-operation and Development (OECD).

[3]National data adjusted by OECD.

[4]Provisional.

[6]Estimated by NSF.

[7]Preliminary.

SOURCES: United States: NSF, *National Patterns of R&D Resources: 1989* (NSF 89-308), p. 39. Other countries: OECD, Scientific, Technological and Industrial Indicators Division, "Main Science and Technology Indicators: 1982-88," Vol. 1, pp. 19-20; and unpublished tabulations.

See figure 6-1.

Science & Engineering Indicators—1989

Appendix table 6-2. Expenditures for industrial R&D, by source of funds: 1960-89

	Current dollars			Constant 1982 dollars[1]		
	Total	Company[2]	Federal Government[3]	Total	Company[2]	Federal Government[3]
	Millions of dollars					
1960	10,509	4,428	6,081	33,955	14,307	19,648
1961	10,908	4,668	6,240	34,917	14,942	19,974
1962	11,464	5,029	6,435	35,892	15,745	20,147
1963	12,630	5,360	7,270	38,981	16,543	22,438
1964	13,512	5,792	7,720	41,032	17,589	23,444
1965	14,185	6,445	7,740	41,992	19,079	22,913
1966	15,548	7,216	8,332	44,474	20,641	23,833
1967	16,385	8,020	8,365	45,590	22,315	23,275
1968	17,429	8,869	8,560	46,194	23,506	22,688
1969	18,308	9,857	8,451	46,023	24,779	21,244
1970	18,067	10,288	7,779	42,986	24,478	18,508
1971	18,320	10,654	7,666	41,280	24,006	17,274
1972	19,552	11,535	8,017	42,056	24,812	17,245
1973	21,249	13,104	8,145	42,893	26,451	16,441
1974	22,887	14,667	8,220	42,415	27,181	15,234
1975	24,187	15,582	8,605	40,781	26,272	14,509
1976	26,997	17,436	9,561	42,805	27,645	15,159
1977	29,825	19,340	10,485	44,330	28,746	15,584
1978	33,304	22,115	11,189	46,115	30,622	15,493
1979	38,226	25,708	12,518	48,652	32,720	15,932
1980	44,505	30,476	14,029	51,919	35,553	16,366
1981	51,810	35,428	16,382	55,140	37,705	17,435
1982	57,995	39,512	18,483	57,995	39,512	18,483
1983	63,403	42,861	20,542	61,047	41,268	19,779
1984	71,470	48,308	23,162	66,342	44,842	21,500
1985	78,269	51,439	26,830	70,544	46,362	24,182
1986	80,631	52,848	27,783	70,772	46,386	24,386
1987 (prel.)	85,500	55,500	30,000	72,661	47,166	25,495
1988 (est.)	90,600	59,100	31,500	74,752	48,762	25,990
1989 (est.)	95,350	62,600	32,750	75,741	49,726	26,015

[1]See appendix table 4-1 for GNP implicit price deflators used to convert current dollars to constant 1982 dollars.

[2]Includes all sources other than the Federal Government.

[3]Data include federally funded R&D centers administered by industry.

Note: Detail may not add to total because of rounding.

Science & Engineering Indicators—1989

Appendix table 6-7. Patent classes most and least emphasized by U.S. corporations patenting in the United States: 1978 and 1988

Class	Class number	1978 activity index	1988 activity index
Most emphasized classes			
1. Mineral oils: processes and products	208	1.82	2.03
2. Wells	166	1.77	1.94
3. Chemistry: analytical and immunological testing	436	1.46	1.48
4. Chemistry: molecular biology and microbiology	435	0.97	1.47
5. Catalyst, solid sorbent, or support therefor, product or process of making	502	1.44	1.46
6. Error detection/correction and fault detection/recovery	371	1.45	1.40
7. Semiconductor device manufacturing: process	437	1.36	1.40
8. Part of the class 520 series—synthetic resins or natural rubbers	521	1.23	1.40
9. Glass manufacturing	065	1.16	1.38
10. Electrical connectors	439	1.56	1.37
11. Amplifiers	330	1.03	1.36
12. Pulse or digital communications	375	1.13	1.36
13. Multiplex communications	370	0.91	1.33
14. Surgery	604	1.15	1.33
15. Electrical computers and data processing systems	364	1.35	1.32
16. Part of the class 520 series—synthetic resins or natural rubbers	525	1.33	1.32
17. Drug, bioaffecting and body treating compositions	424	1.17	1.31
18. Food or edible material: processes, compositions, and products	426	1.18	1.30
19. Part of the class 520 series—synthetic resins or natural rubbers	528	1.28	1.29
20. Compositions	252	1.33	1.29
Least emphasized classes			
1. Fishing, trapping, and vermin destroying	043	0.38	0.22
2. Motor vehicles	180	0.95	0.35
3. Amusement devices, games	273	0.48	0.39
4. Dynamic information storage or retrieval	369	0.63	0.43
5. Photography	354	0.49	0.43
6. Internal combustion engines	123	0.54	0.46
7. Land vehicles	280	0.55	0.55
8. Ships	114	0.47	0.56
9. Amusement and exercising devices	272	0.38	0.56
10. Dynamic magnetic information storage or retrieval	360	0.89	0.57
11. Typewriting machines	400	1.20	0.60
12. Winding and reeling	242	0.78	0.61
13. Machine elements and mechanisms	074	0.92	0.64
14. Geometrical instruments	033	0.59	0.64
15. Photocopying	355	0.97	0.66
16. Tools	081	0.79	0.67
17. Chairs and seats	297	0.88	0.67
18. Dentistry	433	0.76	0.69
19. Radiation imagery chemistry—process, composition, or product	430	1.11	0.72
20. Plastic article or earthenware shaping or treating: apparatus	425	0.92	0.73

Notes: The activity index is the percent of the patents in a class that are granted to U.S. inventors and owned by U.S. corporations, divided by the percent of all patents that have U.S. inventors and U.S. corporate owners in that year. Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988.

Science & Engineering Indicators—1989

Appendix table 6-8. Patent classes most and least emphasized by Japanese inventors patenting in the United States: 1978 and 1988

Class	Class number	1978 activity index	1988 activity index
Most emphasized classes			
1. Photocopying	355	2.60	3.23
2. Dynamic information storage or retrieval	369	3.40	3.14
3. Dynamic magnetic information storage or retrieval	360	3.28	3.08
4. Photography	354	4.83	3.07
5. Radiation imagery chemistry—process, composition, or product	430	2.93	2.64
6. Recorders	346	1.76	2.62
7. Typewriting machines	400	1.17	2.46
8. Static information storage and retrieval	365	1.41	2.46
9. Pictorial communication; television	358	2.24	2.43
10. Motor vehicles	180	0.95	2.34
11. Internal combustion engines	123	3.09	2.29
12. Active solid-state devices e.g., transistors, solid-state diodes	357	2.13	1.90
13. Machine elements and mechanisms	074	1.37	1.88
14. Clutches and power-stop control	192	1.01	1.77
15. Electricity, motive power systems	318	1.73	1.73
16. Electrical generator or motor structure	310	1.79	1.69
17. Registers	235	1.45	1.68
18. Optics, systems and elements	350	1.69	1.63
19. Stock material or miscellaneous articles	428	1.33	1.62
20. Metal treatment	148	2.04	1.57
Least emphasized classes			
1. Aeronautics	244	0.04	0.05
2. Wells	166	0.00	0.07
3. Ammunition and explosives	102	0.14	0.07
4. Prothesis (i.e., artificial body members), parts thereof or aids and accessories therefor	623	0.00	0.09
5. Bottles and jars	215	0.43	0.09
6. Amusement and exercising devices	272	0.08	0.15
7. Fishing, trapping, and vermin destroying	043	0.54	0.15
8. Static structures, e.g., buildings	052	0.33	0.21
9. Surgery	604	0.14	0.21
10. Beds	005	0.05	0.23
11. Geometrical instruments	033	0.50	0.24
12. Tools	081	0.08	0.25
13. Hydraulic and earth engineering	405	0.77	0.28
14. Stoves and furnaces	126	0.17	0.29
15. Mineral oils: processes and products	208	0.23	0.31
16. Cleaning and liquid contact with solids	134	0.62	0.31
17. Special receptacle or package	206	0.26	0.34
18. Induced nuclear reaction, systems and elements	376	0.59	0.34
19. Receptacles	220	0.46	0.35
20. Dispensing	222	0.39	0.37

Notes: The activity index is the percent of the patents in a class that are granted to Japanese inventors, divided by the percent of all patents that have Japanese inventors in that year. Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988.

Science & Engineering Indicators—1989

Appendix table 6-9. Patent classes most and least emphasized by West German inventors patenting in the United States: 1978 and 1988

Class	Class number	1978 activity index	1988 activity index
Most emphasized classes			
1. Printing	101	1.79	2.55
2. Chemistry, fertilizers	071	1.11	2.37
3. Part of the class 532-570 series—organic compounds	548	1.32	2.31
4. Ammunition and explosives	102	1.60	2.27
5. Part of the class 532-570 series—organic compounds	568	1.53	2.05
6. Part of the class 532-570 series—organic compounds	560	1.39	1.96
7. Solid material comminution or disintegration	241	1.87	1.87
8. Plastic article or earthenware shaping or treating: apparatus	425	1.79	1.85
9. Part of the class 520 series—synthetic resins or natural rubbers	528	1.82	1.84
10. Brakes	188	1.81	1.83
Least emphasized classes			
1. Fishing, trapping, and vermin destroying	043	0.14	0.00
2. Wells	166	0.07	0.12
3. Amusement and exercising devices	272	0.19	0.16
4. Mineral oils: processes and products	208	0.27	0.17
5. Amusement devices, games	273	0.05	0.19
6. Beds	005	0.41	0.20
7. Photocopying	355	1.02	0.23
8. Recorders	346	1.30	0.25
9. Communications, radio wave antennas	343	0.14	0.26
10. Photography	354	1.71	0.31

Notes: The activity index is the percent of the patents in a class that are granted to West German inventors, divided by the percent of all patents that have West German inventors in that year. Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988.

Science & Engineering Indicators—1989

Appendix table 6-10. Patent classes most and least emphasized by French inventors patenting in the United States: 1978 and 1988

Class	Class number	1978 activity index	1988 activity index
Most emphasized classes			
1. Induced nuclear reactions, systems, and elements	376	2.89	4.65
2. Clutches and power-stop control	192	1.10	2.36
3. Ammunition and explosives	102	0.66	2.32
4. Pulse or digital communications	375	2.04	2.25
5. Rotary kinetic fluid motors or pumps	415	0.57	2.21
6. Brakes	188	2.41	2.12
7. Pipe joints or couplings	285	0.67	2.12
8. Part of the class 532-570 series—organic compounds	560	0.51	2.10
9. Aeronautics	244	1.87	1.93
10. Electricity, electrical systems, and devices	361	0.89	1.90
Least emphasized classes			
1. Amusement and exercising devices	272	0.00	0.00
2. Photocopying	355	0.32	0.05
3. Chemistry, fertilizers	071	0.48	0.09
4. Beds	005	0.16	0.14
5. Radiation imagery chemistry—process, composition, or product	430	0.17	0.22
6. Fishing, trapping, and vermin destroying	043	0.20	0.22
7. Abrading	051	0.62	0.22
8. Land vehicles, bodies, and tops	296	0.17	0.23
9. Photography	354	0.19	0.23
10. Geometrical instruments	033	0.50	0.25

Notes: The activity index is the percent of the patents in a class that are granted to French inventors, divided by the percent of all patents that have French inventors in that year. Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988.

SOURCE: U.S. Patent and Trademark Office, Office of Documentation Information, *Country Activity Index Data*, report prepared for NSF (June 1989).

Science & Engineering Indicators—1989

Appendix table 6-11. Patent classes most and least emphasized by British inventors patenting in the United States: 1978 and 1988

Class	Class number	1978 activity index	1988 activity index
Most emphasized classes			
1. Brakes	188	2.38	3.14
2. Glass manufacturing	065	2.31	2.27
3. Drug, bioaffecting and body treating compositions	514	2.14	2.20
4. Hydraulic and earth engineering	405	2.22	2.08
5. Multiplex communications	370	0.49	1.98
6. Compositions	252	1.45	1.86
7. Drug, bioaffecting and body treating compositions	424	1.98	1.85
8. Part of the class 532-570 series—organic compounds	568	0.93	1.85
9. Power plants	060	1.14	1.80
10. Aeronautics	244	1.12	1.77
Least emphasized classes			
1. Electrical audio signal processing and systems, and devices	381	1.66	0.00
2. Dynamic information storage or retrieval	369	0.73	0.20
3. Fishing, trapping, and vermin destroying	043	0.00	0.23
4. Mineral oils: processes and products	208	0.50	0.24
5. Dentistry	433	0.27	0.28
6. Tools	081	0.82	0.28
7. Illumination	362	0.88	0.32
8. Photography	354	0.25	0.32
9. Recorders	346	0.28	0.36
10. Electrical transmission or interconnection systems	307	0.80	0.37

Notes: The activity index is the percent of the patents in a class that are granted to British inventors, divided by the percent of all patents that have British inventors in that year. Listing is limited to U.S. patent office classes that received at least 200 patents, from all countries, in 1988.

Total	100	100	100	100

[1]Independent businesses comprised of one or more establishments.

[2]Independent businesses with fewer than 500 employees.

[3]Independent businesses with 500 or more employees.

[4]All establishments in data base whether independent or part of a larger business. SOURCE: Derived from the CorpTech data base, Corporate Technology Information Services, Inc., Wellesley Hills, MA (Rev 3.3, March 1989).

See figure 6-6.

Science & Engineering Indicators—1989

Appendix table 6-15. Revenues of companies active in high-tech fields, operating in the U.S.: 1989

Revenue	Number of companies	Percentage of total
Under $1 million	6,191	24
$1 - 2.5 million	4,622	18
$2.5 - 5 million	3,313	13
$5 - 10 million	2,945	11
$10 - 25 million	3,028	12
$25 - 50 million	1,604	6
$50 - 100 million	1,033	4
$100 - 250 million	962	4
$250 - 500 million	523	2
over $500 million	1,822	7
Total	26,043	100

Note: Not all companies in the CorpTech data base reported revenues.

SOURCE: Derived from the CorpTech data base, Corporate Technology Information Services, Inc., Wellesley Hills, MA (Rev 3.3, March 1989).

Science & Engineering Indicators—1989

Appendix table 6-16. Ownership of companies active in high-tech fields operating in the U.S., by country of ownership: March 1989

Country	All high-tech companies	Biotechnology companies
	Number	
United States	27,709	635
Foreign-owned	2,312	82
United Kingdom	736	19
Japan	480	12
West Germany	471	15
France	209	2
Canada	185	1
Switzerland	172	6
The Netherlands	132	8
Sweden	112	3
East Asian NICs[1]	40	1
Total	30,021	717
	Percent	
United States	92	89
Foreign-owned	8	11
United Kingdom	2	3
Japan	2	2
West Germany	2	2
France	1	([2])
Canada	1	([2])
Switzerland	1	1
The Netherlands	([2])	1
Sweden	([2])	([2])
East Asian NICs[1]	([2])	([2])
Total	100	100

[1]East Asian newly industrialized countries include Hong Kong, Singapore, South Korea, and Singapore. The one biotechnology company is owned by South Korea.

[2]Less than 0.05 percent.

[1]Industries whose products meet the DOC-3 criteria for high-technology products. See U.S. Department of Commerce, International Trade Administration, *An Assessment of U.S. Competitiveness in High Technology Industries* (Washington, DC: Government Printing Office, 1983) pp. 33-37.

[2]Service industries identified by the U.S. Small Business Administration as high technology, but excluding "Business services, N.E.C." and "Service industries, N.E.C."

Note: A small business is defined as an independent company that has less than 500 employees or a company that is part of a larger enterprise that has less than 500 employees.

Science and Engineering Indicators—1989

Appendix table 6-21. Venture capital resources, commitments, and disbursements: 1978-87

	Net new private capital committed to venture capital firms[1]	Total pool of capital under management	Disbursements excluding SBIC straight debt lending[2] and leveraged buyout financing
	Millions of dollars		
1978	600	3,500	332
1979	300	3,800	665
1980	700	4,500	799
1981	1,300	5,800	1,171
1982	1,800	7,600	1,566
1983	4,500	12,100	2,457
1984	4,200	16,300	2,651
1985	3,300	19,600	2,272
1986	4,500	24,100	2,217
1987	4,900	29,000	3,281

[1]Total new private capital less capital withdrawals.

[2]Debt financing by licensed Small Business Investment Corporations.

Note: Data describe resources of venture capital firms reporting to Venture Economics, Inc. In 1984-85, the Venture Economics data base covered about 600 U.S. venture capital firms.

SOURCE: Venture Economics, Inc., special tabulations prepared for NSF.

See figure 6-8.

[1]Early stage investment includes capital to develop prototypes, begin production, and initiate marketing. Research and development partnerships to launch new businesses are included.

[2]Later stage investment provides capital for the expansion of firms that are already producing and marketing products. It includes bridge financing for firms that are going public, as well as research and development partnerships that fund new product development by established firms.

See figure 7-4.

Science & Engineering Indicators—1989

Appendix table 7-8. U.S. market share for high-tech products: 1970-86

U.S. share[1]	1970	1980	1982	1984	1985	1986
	Percent					
Global market	51.0	41.0	47.0	48.0	51.0	42.0
U.S. home market	94.5	88.2	87.8	83.7	83.6	81.8
Foreign markets	10.1	11.9	14.3	14.6	16.1	11.1

[1]U.S. share of the global market represents U.S. production as a share of total Organisation for Economic Co-operation and Development production. Foreign markets are estimated by subtracting total U.S. consumption from global shipments (OECD production). U.S. share of foreign markets represents U.S. exports' share of these foreign markets.

Note: As identified by the OECD definition of "high intensity technology products" and the Department of Commerce's DOC-3 definition.

SOURCES: Organisation for Economic Co-operation and Development, Industrial Outlook Database (July 1988 and December); U.S. Department of Commerce, International Trade Administration, *United States Trade Performance in 1987*; and U.S. Department of Commerce, International Trade Administration, Office of Trade and Investment Analysis, unpublished data.

See figure O-22 in Overview.

Science & Engineering Indicators—1989

Appendix table 7-9. U.S. exports of high-tech and other manufactured products as a percentage of shipments: 1978-86

Product group	1978	1979	1980	1981	1982	1983	1984	1985	1986
	Ratio of exports to product shipments								
	Percent								
All manufactured products[1]	6.2	6.8	8.4	8.3	7.9	7.0	7.0	7.1	8.0
All high-technology products[2]	18.1	19.7	20.5	20.4	18.7	16.5	17.2	17.3	17.7
Guided missiles and spacecraft	8.4	6.9	7.5	4.7	8.5	6.6	5.5	4.7	3.4
Communications equipment & electronic components	14.0	17.8	15.3	15.1	14.2	11.4	15.9	12.0	13.0
Aircraft and parts	35.3	31.6	33.6	35.8	30.3	24.2	25.6	27.9	25.8
Office and computing machines	25.1	25.7	28.3	27.7	25.2	21.3	32.1	27.6	30.0
Ordnance and accessories	21.5	23.9	20.7	18.9	18.0	22.7	19.5	15.0	15.0
Drugs and medicines	12.2	10.4	11.2	11.2	10.2	10.2	9.9	9.2	10.1

[1]The market condition of recent price and currency changes in markets outside the United States is said to be "favorable" for the U.S. to expand its exports if the combined effect has been to cause U.S. prices to drop much more rapidly—or increase much more slowly—relative to the average price of goods from all other sources. The combined effort is said to be "somewhat favorable" if the relative change in U.S. prices was only slightly less than the average price change of goods from all other sources. The combined effect is said to be "unfavorable" if U.S. prices increased more rapidly than the average price for goods from all other sources.

[2]Prospects for gains for U.S. manufactured products in the U.S. market is said to be "favorable" if the recent price and currency changes have caused prices of goods from major foreign suppliers to increase much more rapidly or decrease much more slowly relative to the average price of all other goods sold in the United States. The effect is said to be "somewhat favorable" if it has caused import prices to increase slightly faster relative to the average price of all other goods sold in the United States. The effect is said to be "unfavorable" if import prices increased more slowly or dropped relative to the average price of goods from all other sources.

Science & Engineering Indicators—1989

Appendix table 8-1. U.S. and British publics' knowledge of scientific terms: 1988

Term	U.S.	Britain
	—Percent—	
Computer software		
Understands	27	26
Some understanding	9	8
Wrong or vague	17	1
Don't know/not asked	47	65
DNA		
Understands	22	13
Some understanding	10	15
Wrong or vague	5	5
Don't know/not asked	63	67
Radiation		
Understands (scientific understanding)	6	NA
Some understanding (knows effects or impacts)	25	NA
Wrong or vague	39	NA
Don't know/not asked	31	NA
N =	2,041	2,009

U.S. wording: "Computer software. When you read or hear the term 'computer software' do you have a clear understanding of what it means, a general sense of what it means, or little understanding of what it means?"

IF CLEAR UNDERSTANDING OR GENERAL SENSE: "Please tell me, in your own words, what is computer software?"

British wording: "Would you say you had a good, fair, or poor understanding of the computer terms 'hardware' and 'software'?"

IF GOOD OR FAIR: "What is computer software?"

U.S. wording: "In articles and on television shows, the term 'DNA' has been used. When you hear the term 'DNA', do you have a clear understanding of what it means, a general sense of what it means, or little understanding of what it means?"

IF CLEAR UNDERSTANDING OR GENERAL SENSE: "Please tell me, in your own words, what is DNA?"

British wording: "When scientists use the term DNA, do you think it is to do with the study of stars, rocks, living things, or computers?"

IF "LIVING THINGS": "What is DNA?"

NA = Not asked.

See figure 8-1.

Science & Engineering Indicators—1989

Appendix table 8-12. Detailed responses to question about dangerous powers possessed by scientists: 1988

Area mentioned	Responses included
Nuclear	Nuclear science, nuclear power, nuclear weapons, radiation
Biological	Experiment on people, dangerous medical advances, genetic engineering, test tube babies, control people
Weapons	Weapons, bombs (no mention of nuclear), explosive materials, war, germ warfare
Individual quirks	Quirks of scientists (disloyal, mad, withhold information, greedy)
Chemicals	Chemicals, toxic chemicals
Environmental effects	Environmental, disturbing space
Religion	Challenge religion

"When you think about scientific researchers who have powers that make them dangerous, what kinds of powers do you have in mind?"

SOURCE: J.D. Miller, "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See text table 8-12.

Science & Engineering Indicators—1989

Appendix table 8-13. Public preference for problem areas on which government funds should be spent: 1988

Problem area	Too little	Right amount	Too much	Don't know
	Percent			
Helping older people	76	21	2	1
Improving education	76	19	4	1
Reducing pollution	76	18	4	2
Improving health care	67	28	2	2
Helping low-income persons	55	30	12	3
Supporting scientific research	34	48	15	4
Exploring space	17	38	43	2
Improving national defense[1]	17	42	38	3
Developing weapons for national defense[1]	11	35	52	3
N =	2,041			

"We are faced with many problems in this country. I'm going to name some of these problems, and for each one, I'd like you to tell me if you think that the government is spending too little money on it, about the right amount, or too much."

[1]The sample was divided so that 999 answered this question with the first wording and 1,042 answered it with the second wording.

Note: Percentages may not add to 100 because of rounding.

SOURCE: J.D. Miller, "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See text table 8-13.

Science & Engineering Indicators—1989

Appendix table 8-14. Public preferences on regulation of various areas of science and technology: 1988

Area	Too low	About right	Too high	Don't know
	Percent			
Use of chemical additives in foods	42	29	25	3
Construction of nuclear power plants	31	40	24	6
Conduct of genetic engineering research	25	51	9	15
Conduct of basic scientific research	23	60	10	8
Development of new pharmaceutical products	16	63	16	5
N =	2,041			

"I'm going to read you a short list of activities and for each one I'd like for you to tell me whether you think that the present level of governmental regulation is too high, too low, or about right."

Note: Percentages may not add to 100 because of rounding.

SOURCE: Miller, J.D., "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See text table 8-14.

Science & Engineering Indicators—1989

Appendix table 8-15. Public attitudes toward animal research: 1988

	Strongly agree	Agree	Disagree	Strongly disagree	Don't know	N
	Percent					
Total public	5	48	28	14	5	2,041
Men	6	55	26	7	5	958
Women	4	41	30	19	6	1,083
18 to 24	4	43	29	21	3	318
25 to 34	5	45	30	14	5	486
35 to 44	5	47	28	14	6	373
45 to 64	4	52	27	12	6	532
65 and older	6	52	27	8	6	332
Less than H.S. graduate	3	53	26	12	6	530
H.S. graduate or some college	5	44	31	16	5	1,155
College graduate	8	53	23	9	6	356

"Scientists should be allowed to do research that causes pain and injury to animals like dogs and chimpanzees if it produces new information about health problems."

Note: Percentages may not add to 100 because of rounding.

SOURCE: J.D. Miller, "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See text table 8-15.

Science & Engineering Indicators—1989

Appendix table 8-16. Public attitudes toward space exploration and nuclear power: 1988

Area and subpopulation	Benefits strongly exceed costs	Benefits only slightly exceed costs	Costs only slightly exceed benefits	Costs strongly exceed benefits	About the same or don't know[1]	N
	Percent					
Space exploration						
Total public	22	24	18	26	11	2,041
Men	28	26	13	22	11	958
Women	16	22	22	29	12	1,083
18 to 24	19	30	20	25	8	318
25 to 34	21	26	17	25	10	486
35 to 44	23	25	17	23	12	373
45 to 64	23	24	15	24	14	532
65 and older	20	13	19	32	16	332
Less than H.S. graduate	15	25	20	29	11	530
H.S. graduate or some college	21	23	17	27	12	1,155
College graduate	33	23	15	16	13	356
	Benefits strongly exceed risks	Benefits only slightly exceed risks	Risks only slightly exceed benefits	Risks strongly exceed benefits	About the same or don't know[1]	N
Nuclear power						
Total public	18	23	17	30	12	2,041
Men	23	26	15	28	8	958
Women	13	20	18	32	16	1,083
18 to 24	12	23	28	30	7	318
25 to 34	16	24	19	33	7	486
35 to 44	14	22	18	34	12	373
45 to 64	24	23	13	26	15	532
65 and older	21	23	8	29	19	332
Less than H.S. graduate	15	25	18	25	18	530
H.S. graduate or some college	18	22	17	33	11	1,155
College graduate	22	23	14	32	9	356

"Many current issues in science and techology may be viewed as a judgment of relative risks and benefits, or costs and benefits. Thinking first about the space program, some persons have argued that the costs of the space program have exceeded its benefits, while other people have argued that the benefits of space exploration have exceeded its costs. In your opinion, have the costs of space exploration exceeded its benefits, or have the benefits of space exploration exceeded its costs?" "Would you say that the benefits have substantially exceeded the costs, or only slightly exceeded the costs?" "Would you say that the costs have substantially exceeded the benefits, or only slightly exceeded the benefits?"

"In the current debate over the use of nuclear reactors to generate electricity, there is broad agreement that there are some risks and some benefits associated with nuclear power. In your opinion, are the risks associated with nuclear power greater than the benefits, or are the benefits associated with nuclear power greater than the risks?"

[1]Since some respondents did not answer the questions about benefits slightly or substantially exceeding costs or risks, the number responding "about equal" or "don't know" is greater than on text table 8-16.

SOURCE: J.D. Miller, "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See text table 8-16.

Science & Engineering Indicators—1989

Appendix table 8-17. Effect of the Challenger and Chernobyl accidents on general public attitudes toward science and technology: 1985-88

	November 1985	February 1986	June 1986	July 1988
	Percent			
Beneficial versus harmful effects of scientific research				
Balance strongly favors beneficial results	47	20	22	53
Balance only slightly favors beneficial results	24	59	55	21
About equal[1]	5	4	3	2
Balance only slightly favors harmful results	12	7	5	8
Balance strongly favors harmful results	5	3	8	4
Don't know/no answer	7	6	5	9
Benefits of space program versus costs				
Benefits substantially greater than costs	30	37	33	22
Benefits only slightly greater than costs	25	28	27	24
About equal[1]	3	3	2	3
Costs only slightly greater than benefits	13	9	14	18
Costs substantially greater than benefits	26	16	18	26
Don't know/no answer	5	5	5	9
Benefits of nuclear power versus risks				
Benefits substantially exceed risks	30	23	26	18
Benefits only slightly exceed risks	20	30	26	23
About equal[1]	1	3	2	3
Risks only slightly exceed benefits	13	12	10	17
Risks substantially exceed benefits	31	26	28	30
Don't know/no answer	4	5	7	9
N =	1,111	1,111	1,111	2,041[2]

"Would you say that, on balance, the benefits of scientific research have outweighed the harmful results, or have the harmful results been greater than the benefits?" "Would you say that the balance has been strongly in favor of beneficial results, or only slightly?"

[1]Volunteered by respondents.

[2]For the "scientific research" question, N = 1,042.

Note: The same persons were interviewed in the 1985 and 1986 surveys.

SOURCE: J.D. Miller, "The Impact of the Challenger Accident on Public Attitudes Toward the Space Program," report to the National Science Foundation (January 1987); J.D. Miller, "Attitudes of the U.S. Public Toward Science and Technology: 1988," report to the National Science Foundation (forthcoming, 1989).

See figure O-27 in Overview.
